DR. WILLIAM OSLER,¹ of Montreal, discusses this comparatively rare disease, which has only received attention within the past few years, in connection with seven cases, one in a cow, of which he was cognizant, and all accompanied by autopsies. His paper is instructive and interesting, and is rendered more valuable by carefully executed plates of the microscopical appearances of the endocardial vegetations. We make such extracts from it as space will allow. Under the terms *diphtheritic*, *ulcerative*, *malignant*, *septic*, or *infectious* endocarditis, *arteria pyæmia*, *mycosis endocardii*, physicians now recognize one of the most formidable of cardiac affections, characterized by a peculiar morbid process on the valves, blood contaminations, constitutional symptoms of the typhoid or pyæmic types, and usually associated with multiple emboli.

With regard to the nomenclature, he thinks the terms *infectious* and *septic*, as given by Jaccoud,² better than the others. Against the name *ulcerative* is the fact that there may be no actual ulceration on the valves, and there may be, on the other hand, endocardial losses of substance without the special constitutional disturbances by which the disease is characterized. The term *diphtheritic* is good, in so far as it expresses a resemblance in the histological features of the valvular disease to that of true diphtheritic exudation, but this is scarcely sufficient ground for its use; and it is, in a way, misleading, indicating a relation between diphtheria and the disease which is not known to exist. The name *mycosis endocardii* certainly expresses a striking feature of the local process, but with our present imperfect knowledge of the relation of the micrococci colonies to the disease, such a designation is, to say the least, premature. On the other hand, the term *infectious* presupposes no special view as to the nature of the local process, and at the same time indicates, as Jaccoud says, a constant and exclusive character of the disease.

It would appear that, clinically, three classes of cases are included in the disease known as ulcerative endocarditis, and he thinks it important that a distinction should be made between them. We have:—

(1.) Those cases in which the disease appears without any obvious cause, either spontaneously or in connection with rheumatism or some other affection. The term *infectious* might be applied to this class. It is the *arterial pyæmia* of Wilks, the primary ulcerative endocarditis of some authors.

(2.) Those in which the endocardial disease is secondary to some inflammatory focus—acute necrosis, puerperal endometritis, etc. To these the term *septic* might be applied.

(3.) In certain cases of chronic valvular disease an acute endocardial process may be engrafted (recurrent endocarditis), presenting anatomical features similar to the infectious form, but not characterized by the same clinical picture, the patients dying with the symptoms of chronic heart disease.

The chief points to which Dr. Osler wishes to call

¹ Archives of Medicine, February, 1881, page 44.

² Pathologie Interne, tome i., and Nouveau Dictionnaire, tome iii.

attention, and which are illustrated by the cases are : —

- (1.) That the majority of cases of infectious endocarditis occur independently of rheumatism.
- (2.) The frequency with which infectious endocarditis is associated with pneumonia.
- (3.) The production of acute multiple aneurisms of the aorta in the disease.
- (4.) Certain histological features in the endocardial vegetations, and particularly a remarkable fungoid growth met with in one of the cases.

First. — The fact that *primary infectious endocarditis* in the majority of cases does not occur in connection with acute rheumatism, as is almost universally stated to be the case. Taking the reports of fifty-seven cases of this kind, in only fifteen is there any mention either of *acute rheumatism* or of previous rheumatic attacks, that is, in 26.3 per cent. Though it was not possible for Dr. Osler to make an exhaustive review of the literature of the subject, these cases were gathered from the British and American journals, transactions, hospital reports, and from some of the recent French and German journals. He excluded those due apparently to septic infection, as from whitlow, urethral laceration, acute necrosis, and the puerperal condition. Nor did he include those instances described as ulcerative endocarditis in chronic valvular affections (with dropsy, etc.), class three of above division, often accompanied with aneurisms of the valves; but it may be mentioned in this connection that Dr. Ogile, in the ninth volume of the Transactions of the Pathological Society of London, gives twenty-one cases of aneurism of the valves from ulcerative endocarditis, and of eighteen of these cases in which a history is given, fifteen are distinctly stated not to have had rheumatism. Kirkes,¹ the pioneer in this department of pathology, noticed the fact of its independent occurrence. Dr. Osler confesses to having been considerably surprised at the result of this investigation, as he was previously of the opinion, expressed so strongly by Rosenstein² and others, that the great majority of the cases were met with in connection with acute rheumatism.

The second point to which he directs attention is the frequency with which this disease occurs with pneumonia. He naturally regarded it as not a little remarkable that in five cases in succession this combination should be met with. Cases II., III., IV., and V. appear to have set in with the symptoms of ordinary pneumonia. In Case VI. it did not develop until after the patient had been in hospital for some days. In all the disease appeared to be of the primary lobar form. In Cases III., IV., and V., at the time of the autopsy, the stage of hepatization had passed, and resolution had begun. Of twenty-one cases of primary infectious endocarditis recorded in the Transactions of the Pathological Society of London, hepatization of the lung is mentioned in ten as a concomitant pathological condition. Of the fifty-seven cases which were analyzed, twenty-two were complicated with or occurred in pneumonia, that is, 38.5 per cent. What is the nature of this connection? Is the inflammation of the lung a complication of the endocarditis, or *vice versa*? In most of the cases it is distinctly stated that the lung was hepatized, and in the majority of instances the disease appears to have begun with the symptoms of ordinary pneumonia, so that the

conclusion naturally suggests itself that the endocarditis was either secondary to the pneumonia or excited by the same cause; which latter he thinks the more probable supposition. Endocarditis is scarcely mentioned as a complication of inflammation of the lungs. In Huss's statistics³ there are only four cases mentioned out of 959. The condition of the inflamed part of the lung in Dr. Osler's cases did not present any coarse or microscopical differences from ordinary cases. There were no micrococci in the air-cells, nor any appearances resembling the remarkable bacteritic pneumonia described by Delafield.⁴ It is not very evident wherein the connection lies between these affections, but the very considerable number of instances in which they occur together is against a simple accidental complication.

A third point of clinical interest is the occurrence of meningitis in three of these cases. In the fifty-seven cases which Dr. Osler analyzed this is mentioned as present in thirteen; that is, 22.8 per cent. In seven it occurred with pneumonia. Meningeal hæmorrhage, as in Case V., is mentioned several times. It is probable that the meningitis is embolic, though he did not find micrococci in the exudation. Meningitis is a very rare complication of pneumonia and may occur apart from endocarditis; but in a case of inflammation of the lungs, particularly if the apex is involved (in three out of four such instances he found the upper part of the lung affected), the development of an irregular temperature with cerebral symptoms should suggest the possibility of endocardial mischief, with secondary meningeal inflammation. The exudation in the meninges in these cases is lympho-purulent, not very extensive, and generally on the surface of the hemispheres, not basar.

The presence of multiple aneurisms of the aorta in one case is deserving of comment, as he has not been able to find any similar observation in the literature of either ulcerative endocarditis or of aneurism. The man had evidently been the subject of that peculiar congenital malformation of the aortic semilunar valves which results in the fusion of two segments. In this condition they are very liable to be the seat of a sclerotic endocarditis which terminates in incompetency; and Dr. Osler has met with and described two other cases in which the united curtains, when in this state, were the seat of extensive ulcerative endocarditis.⁵

With regard to the intimate pathology of this disease, it is assumed by most recent writers to be a mycosis, that is, to be dependent upon the growth and propagation of lowly fungi on the valves with a consequent blood contamination. Certainly the minute bodies found in the endocardial vegetations correspond in their chemical and microscopical relations to micrococci. They are motionless, highly refractile spherules, less than a micro-millimeter in diameter, arranged in groups or colonies without any perceptible stroma. Acids, alkalies, ether and chloroform have no effect upon them. These characters are supposed to afford satisfactory means for distinguishing them from granular detritus of an albuminous or fatty nature. Most writers have accepted the view that these bodies are fungoid in nature. Heller,⁶ however, criticises strongly the prevailing conceptions with regard to micrococci, and thinks that there are scarcely any micro-chemical

¹ British Medical Journal, 1863.

³ Quoted by Wilson Fox in Reynolds's System of Medicine.

⁴ Studies in Pathological Anatomy, page 65, Pl. xxxv.

⁵ On fusion of two segments of the aortic valves. Mont. Gen. Hosp. Reports, vol. i. 1880.

⁶ Virchow's Archiv, lxi. 1875.

agents or physical signs by which they can be distinguished from fatty detritus.

Apart from any micro-chemical tests there are peculiarities about these masses which we do not see in any form of fatty degeneration, as the uniformity in size of the granules and their collection into large groups.

The question of the relation of the micrococci to the disease presents many difficulties, and we are probably not yet in a position to give a final answer to the problem. Klebs, and most German writers on the subject, give an unhesitating assent to the parasitic theory and suppose the micrococci to gain access either through the gastro-intestinal or respiratory systems, and they believe them to constitute the actual *materies morbi*. According to Koster¹ and Klebs² not only are these fungi present in the so-called ulcerative form, but they also exist in, and cause the development of, the ordinary warty or bead-like vegetations so frequently met with in the valves. Within the past few months Dr. Osler has examined four specimens of this variety of endocardial vegetation, and has been able to determine in each instance the presence of micrococci, not, it is true, in the same luxuriance, or arranged in definite colonies, but still sufficiently distinctive. In one case of mitral stenosis a fresh vegetation, when teased, showed many closely-packed spherules, some of which were, as Klebs has remarked with reference to the micrococci in this variety, larger than those met with in the ulcerative form. He was greatly struck with the resemblance which certain of these bodies, in this instance, bore to the individual elements of Schultze's granule-masses — those peculiar granular clumps common in blood of some animals and of impoverished persons. These structures are usually regarded as the *débris* of colorless blood corpuscles, but Dr. Osler shows³ that they are aggregations of discoid bodies, probably living organisms of the nature of which we are still ignorant. They do not exist in the form of masses in the blood, but as isolated particles which might readily become adherent to the fresh endocardial outgrowths. This is merely mentioned as a point worthy of future investigation.

It matters little how the micrococci get to the valves, whether by embolism of the small vessels, as Koster supposes, or by deposition on the surface, as Klebs thinks; the question is: Are they responsible by their growth for the peculiar course and malignancy of cases of infectious endocarditis, primary or secondary? The facts of their occurrence in the verrucose form, which may not be accompanied by any symptoms, and of their abundance in the recurrent endocarditis, which attacks old sclerotic valves, are, Dr. Osler thinks, opposed to this view, for if they act as a septic poison in the one case, why should they not do so in the other? The micrococci do not appear to infest the blood in any numbers, so that they must be supposed to distill some subtle poison, "such soon-speeding gear as will disperse itself through all the veins" and profoundly disturb nutrition. The occurrence, however, of fatal septic cases, closely allied to, or identical with those in which a bacteric endocarditis is found, but in which no micrococci can be detected, either in the local process or in the blood, teaches us that the same poison may exist without the intervention of bacteria, the presence of which in any case may be only a partial phenomenon in a general infective process.

CATARRHAL GLAND FEVER.

Under this name Dr. Hugo Engel,⁴ of Philadelphia, reports two cases — out of nine which he had observed — of an affection, not rare, according to his experience, but not described, he thinks, in any of the systematic works on internal medicine, and in books on surgery only some of its symptoms are alluded to, not as forming a distinct and separate disease, but as manifestations of a syphilitic or a scrofulous dyscrasia. Only one of the individuals affected with the disease described was slightly scrofulous, and only one had a doubtful syphilitic taint of the system; Dr. Engel therefore thinks it clear that the association with either diathesis can only be an accidental one. The two cases reported he considers types of the disease, and says: In fact there are only few complaints which, like the one here in question, run, in every individual attacked by it, a so similar course. To recapitulate: A person previously as a rule in perfect health has, after an exposure to cold and damp, chilly sensations, which are followed by increased temperature, fever, and a rapid pulse. Digestion is disturbed; the bowels are sluggish; the urine is highly colored and very acid. From the very beginning of the complaint the patient has pains all over, but especially in and near the inguinal regions; and most of the superficial inguinal and a few of the superficial abdominal glands on both sides of the body are enlarged and painful. One or two of the first named, on either the right or left side, are more inflamed than others, and the integument over them is reddened. All these symptoms continue for about three to five weeks, when one or two of the glands mentioned last suppurate. A day or two later the fever and the digestive disturbances commence to decrease, and then rapidly disappear, leaving the patient in a debilitated condition, from which he only recovers slowly. The weakness in the lower extremities is especially apt to remain a long time. The glands return only very gradually to their normal size, and if the individual affected with this disease has been debilitated before, from any cause whatsoever, or if he be a scrofulous subject, then the illness becomes a much more protracted one, as one after the other of the previously enlarged glands will suppurate. While the glands on both sides are affected only those on one side are apt to suppurate. No other glands of the body, except those alluded to, are ever attacked in this complaint.

The disease cannot be mistaken for any other. The fever and the early acute symptoms, as well as the history of the case, distinguish it from simple scrofulous enlargement and suppuration of glands. The fact of the exposure and the number of glands involved separate it from the bubo of syphilitic or blennorrhagic origin. In lymphadenoma the number of white corpuscles is increased, which is not the case in the disease here described. No other complaint could possibly be taken for the latter.

As regards therapeutics, Dr. Engel's experience has taught him that there exists no abortive treatment of any kind. The disease will run its course, and we can only try to prevent suppuration of more than one gland, to hasten absorption of the morbid products of the others, and to accelerate convalescence. The first object we reach best by keeping the patient in bed until we can be reasonably sure that no more glands will suppurate. He applies, from the first day, hot poultices to those glands which seem doomed to break

¹ Virchow's Archiv, Bd. lxxii.

² Archiv für Exper. Pathol. u. Pharmacol., Bd. ix.

³ Proceedings of the Royal Society, 1875.

⁴ Medical and Surgical Reporter, November 13, 1880, page 421.

down, and sprinkles over each cataplasm the undiluted liquor plumbi subacetatis, to lessen inflammation of the surrounding tissues; all other glands he paints twice daily with the tincture of iodine, until they have been reduced to their normal size. Absorption is further accelerated by bandaging both legs from the knees up, and including the abdomen in the bandaging. The patient is put on an easily digestible but nourishing diet; his bowels are kept open by an occasional blue pill, followed by a saline, and internally he employs, throughout the disease, the mineral acids, a favorite prescription of his being, —

℞ Acidi muriatici diluti	f 3 ss.
Tinct. nucis vomice	f 3 j.
Aque destillate	f 3 iiss.
Syrup. rubi idæi, q. s. ad	f 3 vj. M.

Sig. Unciam dimidium quaque quantâ horâ.

If the fever is high, he gives every second day a single dose of fifteen or twenty grains of quinia in mineral lemonade, the single large dose having a far more favorable influence on the disease than often repeated small doses of the same remedy. The body is twice daily sponged off with tepid water. As soon as the tongue is clear and the fever has subsided, he prescribes the syrup of iodide of iron in twenty-five drop doses three times daily. Abscesses are treated surgically. The moment we attack the glands more vigorously, to hasten either suppuration or absorption, we only prolong the case. In this disease the doctor as well as the patient must have patience. Iodide of potassium and iodoform are useless; mercurial preparations do harm; jaborandi or other diaphoretics debilitate without any benefit, and a tonic treatment with iron, etc., from the beginning, only disturbs digestion more. The best plan to follow is to tell the patient, on the first day, that if he wants to be able to attend to his business again within six weeks — the shortest possible time — he must stay in bed at least for a month, and then act according to the rules laid down.

The disease, Dr. Engel thinks, undoubtedly belongs to the domain of internal medicine, just as leucocythæmia, lymphadenoma, the pest or diphtheria. As in the first the enlarged glands do not constitute the disease, nor in the second the abscesses, nor in the last the throat affection, so is this a constitutional disease, which finds its external expression in enlarged and suppurating glands. And a disease which — almost without warning — will incapacitate an active man (in only such has he seen this complaint) for at least six weeks, for any work, is surely important enough, the writer thinks, to be put on record, and to be thoroughly studied, so that we may, perhaps, at some future time, be able to drop the expectant plan of "noli me tangere," and to cut short this more annoying and painful than dangerous complaint.

As mentioned, the disease seems to attack only adult men, which fact can easily be explained by the causing element, and to be self-limiting, and to affect a person only once. The name proposed for it, "catarrhal gland fever," is perhaps as good as any other.

EXPERIMENTAL RESEARCHES AS TO THE CONNECTION BETWEEN RENAL DISEASE AND CARDIAC HYPERTROPHY.

Grawitz and Israel¹ have performed some experiments upon rabbits to determine the pathological relations between renal disease and cardiac hypertrophy.

¹ Experimentelle Untersuchungen über den Zusammenhang Zwischen Nierenkrankung und Herzhypertrophie, Arch. für path. Anat. u. Phys., lxxxviii, s. 315.

phy, which have a certain bearing upon increased arterial tension in Bright's disease and lithæmia,² as noticed by Mahomed, and upon the mechanical theory of compensation propounded by Traube. The renal affections were produced by a temporary occlusion of the vessels of the kidney. The artery, being exposed and isolated, was compressed by forceps. At the expiration of one or two hours these were removed and the wound was sewed up. The first result in every case of this occlusion of the renal artery was a parenchymatous hæmorrhagic nephritis. The secondary result was at times a renal cirrhosis; at others a parenchymatous nephritis (either the small contracted or the large white kidney), according to circumstances. The first result was obtained with strong, hearty animals; the second, with the feeble and debilitated.

The experimenters proceeded to study the comparative influences resulting from, (1) the renal cirrhosis, (2) the parenchymatous nephritis, (3) extirpation of a kidney. They found that the resulting changes in the organs depended upon the age and condition of the animal and not upon the nature of the artificial lesion set up in the kidney.

In young and growing animals it was observed that the uninjured kidney began to hypertrophy immediately after the operation, and at the same time its functional activity was increased. The result was always the same whether in cirrhosis, parenchymatous nephritis, or extirpation of one of the kidneys; in each case the other kidney developed progressively until attaining the size of two ordinary kidneys, and simultaneously the quantity of urine secreted was doubled, and the animals continued in perfect health. The injured kidney continued to secrete a watery urine of light specific gravity, and small in amount as long as the heart remained unchanged, and in these young animals the heart was always unaffected. Among the old and developed animals, on the other hand, the compensating hypertrophy of the sound kidney was less marked, slow in establishing itself, and always insufficient. Upon removing the left kidney, for example, which weighed 5.3 grams, it was found that the right kidney at the end of nine days weighed only 8.1 grams.

The experimenters then proceeded to study the effect of this deficiency upon the system. They found that, (1) some of the animals died from nremia; (2) some lived, though in a miserable condition, showing that this deficiency remained uncompensated; (3) some lived and continued in good health, and among the animals of this third category hypertrophy of the left ventricle was always found. Messrs. Grawitz and Israel express the general result of these changes by the following formula: hypertrophied heart + hyper. kidney = two healthy kidneys + healthy heart. In discussing the question of the first cause of the cardiac participation in these changes these writers are not disposed to regard it as simply a mechanical matter, but think rather that the small quantity of urine contained in the blood after the affection of one kidney excites first the other kidney and then the heart to exaggerated action, thus subsequently causing hypertrophy. They found that neither extreme stages of renal atrophy, nor parenchymatous nephritis, nor removal of the kidney, produced increased arterial tension, however great the changes effected in the heart. It was found that the injection of small quantities of urea into the blood produced the constant result of exaggeration of the action of the heart.

(To be continued.)

Hospital Practice and Clinical Memoranda.

PERINEPHRITIC ABSCESS.

BY W. G. FROST, M. D., DANVERSPORT, MASS.

W. A. T., thirty-seven years old, single, took a severe cold October 26, 1880, for which he received domestic treatment till November 20th. I found him sitting up and dressed, much emaciated, no appetite, pulse 88, temperature $101\frac{3}{4}^{\circ}$ F., tongue coated, and with the general appearance and make up of consumption. He had no cough nor thoracic pain. He complained of pain in the right loin with tenderness, of pain without tenderness over the lesser trochanter. He had no pain along the ureter, no numbness of the thigh, and the urine though of high color was normal in quantity and in specific gravity with neither pus nor albumen. The right thigh was partly flexed and he walked with difficulty. He was told that he had inflammation, with pus forming, around the right kidney. The symptoms gradually increased, and at the end of ten days swelling, with obscure fluctuation, appeared in the back.

December 3d. Obtained four ounces of thick gelatinous and effusive pus, by aspiration.

December 6th. Obtained by aspiration twelve ounces of pus same in character as before.

December 9th. Eight ounces of pus by aspiration. Patient is weaker, pulse 100, no appetite. He has now a suspicious cough with expectoration and night sweats.

December 12th. Opened the abscess by an incision one inch long and three inches deep. Two and a half pints of pus were discharged. A drainage tube was inserted and the cavity was washed with carbolic acid solution.

December 13th. Is weaker, kept his bed all day, pulse 120.

December 18th. Have used the carbolic acid solution twice daily since the 12th. Abscess has discharged but two or three ounces daily since it was opened and is healing, pus laudable. The cough and expectoration have increased, chills alternate with fever, night sweats continue, both feet are badly swollen, emaciation extreme, pulse 90-120, and he requires a crutch and cane to walk. The presence of tubercles in the interscapular region is plain.

December 22d. Removed the rubber tube.

December 29th. Patient is improving. Wound is healed. Walks without crutch or cane.

January 21st. Gaining slowly. Rode out to-day. Is gaining in weight.

February 9th. Gaining steadily. Has ridden out several times, some days when the thermometer was but a few degrees above zero. Appetite has improved, cough is better, no night sweats, swelling gone from the feet. Left this morning, by railroad, for his home, in Nova Scotia.

March 5th. He writes that he reached home all right, and, though somewhat weak and coughing somewhat, is still gaining and weighs one hundred and sixty-four pounds, twenty-four pounds more than he weighed December 20.

The treatment from the outset was supporting, — beef, milk, eggs, cod-liver oil, and Murdock's food.

March 19, 1881.

MORPHIA HABIT.

BY J. A. LOVELAND, M. D., WESTMORELAND, N. H.

MRS. D., aged some thirty-five years, of nervous temperament, had been a morphine habitué six years but resolved to be one no longer. Quantity used by the mouth twelve grains daily. Treatment commenced January 28th by deprivation. First thirty hours the patient was comfortable. January 29th. In the evening was very restless; was suffering acute pain; mind clouded but would answer direct question. January 30th. Still restless except when under the effect of narcotics. Bowels moved by magnesiae sulphas. January 31st. By reason of vomiting passed an uncomfortable night. Mind clear. Neuralgic pains in all parts of the body. February 1st. Vomiting alternating with diarrhoea, which yielded to treatment on the following day. February 3d. Is exhausted, no appetite, thinks she is dying. Some of the time has had no desire for morphine, but now has a craving for it. On consultation with my friend, Dr. G. C. Hill, it was decided to give morphia in grain doses every six hours in connection with a tonic. Stimulants freely. February 4th. The effect of the morphia was almost magical. She had a good appetite, is strong compared with her condition yesterday, cheerful and has no distressing symptoms. Is to take one quarter grain of morphia every six hours with tonics. February 8th. Condition has improved so much that morphine is discontinued. February 9th. Feeling so well to-day that but little narcotic medicine was taken. Takes milk freely. February 12th. Slight delirium at night. General condition encouraging. February 13th. Takes nourishment freely. Slept considerably. February 15th. Is cheerful, rested well through the night and is receiving the tonic effect of the large doses of quinia she has been taking. Pulse 85 and full. In the evening her husband assisted her to some milk when she fell back and instantly expired. The nervines used as her condition required were bromide of potash, belladonna, chloral, and cannabis indica. Much attention was paid to the proper administration of stimulants, tonics, and nutrients. The fatal termination was unexpected. If death had taken place in consequence of cardiac asthenia, the cause which most readily suggests itself, I should suppose it would have been present in some degree at my morning visit. No autopsy.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, M. D., SECRETARY.

FEBRUARY 26, 1881. DR. R. M. HODGES in the chair. DR. A. N. BLODGETT read a paper entitled

THE COLLODION TREATMENT OF STRAINS AND SPRAINS.¹

In reply to a question by Dr. Bradford as to the number of coats required, DR. BLODGETT said that no absolute rule had been followed; he first applied the collodion over the most swollen parts, and then continued it outwards to the uninjured portions. By this time the central part was firm, and the process was then repeated. There were probably six to eight coatings in all.

¹ Vide this journal, page 292.

DR. BRADFORD questioned whether any amount of contracting force could be exerted by the collodion applied in this way, and whether the diminution of swelling might not be due to the cold produced by the evaporation of the ether. He also doubted the possibility of compression without subsequent oedema of the toes.

DR. BLODGETT replied that he considered the compression different in character from that exerted by a bandage. It was a compression in all possible directions, diminishing the extent of surface, and thereby the depth and extent of the inflammatory process. He did not think it was due to ether evaporation, which lasted but a moment, and, moreover, had not been proved to diminish the size of inflamed parts.

DR. J. J. PUTNAM suggested that the absence of oedema might be due to the fact that the pressure was equable at all points. The complete closure of one vein would probably cause more oedema than a slight compression of many. Assuming that contraction ceased after a short time, and therefore compression was not extreme, and also that a certain amount of serum was exuded as a result of pressure, then it was probable that the blood-vessels had more room, and the equilibrium of the circulation would be re-established. Dr. Putnam also spoke of the great value of massage in the treatment of sprains.

DR. MARCY referred to the treatment of sprains by immobilization with a plaster bandage, and thought the principle the same and the resulting cure as speedy; that collodion, however, possessed great advantages over this method if the results obtained were as good. He inquired whether the collodion treatment was not applicable to affections of the knee-joints.

DR. BLODGETT replied that he had not as yet used it for that purpose.

DR. E. M. BUCKINGHAM suggested that the absence of oedema might be due to the elasticity of that part of the skin not encircled by the collodion, which allowed sufficient distention for the establishment of the circulation, thus virtually putting the ankle in an elastic bandage.

DR. BLODGETT admitted that this might be partially true, but thought that the chief action was a local one, relieving distention by an exudation of serum. In reply to a question by Dr. Ayer, Dr. Blodgett said a renewal of the coating was usually required about every twenty-four hours, it being indicated whenever the film showed a tendency to crack or peel off.

DR. BARNES spoke of the strong contractile power of collodion, as evidenced by its ability to bring into and keep in apposition the gaping edges of wounds.

DR. J. J. PUTNAM read a paper on

STRETCHING THE FACIAL NERVE FOR THE CURE OF FACIAL SPASM.¹

He stated that this operation had been performed four times, and in three of these cases at least had been eminently successful, the other not having been finally heard from. The cases treated in this way are those of the class called constitutional or idiopathic, because no cause for the spasm can be found. The operation consists in dissecting down to the nerve in question, hooking it up, and exerting traction with a considerable degree of force. The immediate effect is paralysis, which may persist for several months. In the case presented by Dr. Putnam it lasted about two months, then disappeared rapidly, and at the end of nearly

nine months the spasm had not returned. From experiments on a dog Dr. Putnam had found that the aural branch of the facial nerve broke at a weight of forty pounds, and paralysis of the facial branch—which, however, had begun to pass away on the second day after the operation—was caused by a weight of eight pounds. The necessity of guaging the force to be applied was insisted upon, and also that the patient should be allowed to partially recover from the effects of the ether during the stretching, that the immediate effect might be noted.

DR. S. G. WEBBER referred to a case he had seen where the apparent exciting cause was looking at a bright light. He said that the only other method of treatment giving even partial success was by electricity. The chances of permanent paralysis following this operation he considered comparatively slight. The success hitherto of this procedure for the relief of facial spasm had been very encouraging. For the relief of neuralgia the general operation of nerve stretching in the different nerves affected had been very striking. Dr. Webber referred to a case where paralysis had followed the extraction of a wisdom tooth.

DR. CHENERY spoke of a case of puerperal albuminuria where a very large percentage of albumen was present, and asked the society as to the indications for treatment.

DR. MARCY spoke of a case in which artificial delivery had been accomplished, and where, the woman dying eight hours afterwards, a fatty degeneration of the capillaries of the kidneys was found. He wished to inquire if others had met with this condition, as it was one not usually spoken of.

DR. REYNOLDS referred to the recognized fact that many women have albuminuria without eclampsia. Forty-one per cent. of all women confined have albuminuria. Treatment should be directed towards securing (1) sound sleep, to guard against puerperal mania. (2) Quiet of mind. It is a well-recognized fact that mental disturbance increases the liability to eclampsia. (3) Perfect digestion.

Dr. Reynolds spoke of a fact which had been insisted on by Dr. W. L. Richardson, namely, that the risk of eclampsia is in direct relation to a decrease in the amount of urine for the few days preceding confinement. When the urine does not fall below sixteen ounces the liability to eclampsia is not marked. Dr. Reynolds also said that a hamorrhage a few days previous to labor seemed to act as a safety valve.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

CANCER OF THE UTERUS.

OCTOBER 9, 1880. DR. BLAKE read a paper on the above subject.

DR. DOE criticised his own method of operating, in the case reported by Dr. Blake, as follows:—

Instead of depending upon the curette and the use of caustics afterwards, as he did then, he would now remove as much of the growth as possible by the electro-cautery, the wire being kept from a white heat and slowly drawn through; the remainder of the growth he would remove by the curette, and then apply thoroughly the electro-cautery at a red heat to the diseased parts.

¹ Vide Archives of Medicine, January, 1881.

This last method, he said, is that followed by Dr. John Byrne, of New York, who claims for it that it protects better against secondary hemorrhage than even the curette, and that the tendency to recurrence is infinitely less than by any other method, as its application tends to destroy the disease in its fine and deeply penetrating ramifications.

He reports one case where the whole interior of the cervix and a portion of the body was removed, and the patient remained well six years later.

A second case where a vegetating cancer was removed from the cervix in 1874, by what method not stated, and returned again in five months so as to completely fill up the upper half of the vagina and extended into the body of the uterus to within an inch of the fundus, was removed by the galvanic cautery, and there was no return six years later.

A third case, involving the whole cervix and portion of the body, in a person greatly reduced, was operated upon in this manner, the parts being touched with a dome-shaped cautery, and there was no indication of the disease returning two years later.

As regards the injury to the peritoneum which accidentally occurred in one of the cases reported by Dr. Blake, Dr. Doe remarked that the experience of such men as Goodell and Carl Brown shows it to be of much less serious import than was at first supposed. Dr. Goodell says that he has repeatedly made an opening into the peritoneum without any ill results following, and he quotes Brown as saying that, in order to have the wire pass through healthy tissue, he does not hesitate to include a portion of the peritoneum.

Dr. BAKER reports four cases recently, where, in operating for the removal of a cancerous growth from the uterus, he opened into the peritoneum and no ill results followed; in one case the opening was so large that the whole body of the uterus could be seen.

Dr. DOE reported the following case as illustrating the insidious manner in which the disease often manifests itself. A lady forty-two years of age had traveled extensively through India during the winter months, returned to Boston in the spring feeling perfectly well, and continued so until her return from the country in September. At this time, without pain or any exciting cause whatever, the catamenia continued longer than usual, and, not ceasing at the end of three weeks, a vaginal examination showed the uterus to be fixed and the whole cervix one mass of cancer involving also the posterior wall of the vagina for nearly an inch. The patient lived but six months after the disease was detected.

Dr. MINOT said it was rarely that a case was seen sufficiently early for successful surgical treatment, although much temporary benefit might sometimes be obtained even in advanced cases. In one instance, in which he had removed nearly the whole cervix by the galvano-cautery, the disease reappeared in the stump in the course of a few months. After a thorough application of the incandescent porcelain tip, a temporary arrest was again obtained. The same application was afterwards made again, but the disease invaded the neighboring parts and the woman died within a year. In a case of soft cancer, attached to the anterior wall of the uterus, just above the cervix, the tumor was removed, but returned in a few weeks. It was again removed, but similar growths were found attached to the interior of the womb in various places. These were all removed as carefully as possible, the entire inner

surface of the womb was thoroughly scraped with the finger-nail, and a solution of perchloride of iron was freely applied. The disease returned, as before, but the patient lived nearly two years from the date of the first symptoms. The autopsy showed the cervix and lower part of the body of the womb destroyed by ulceration, only about one fourth of the organ being left. The neighboring parts were also invaded.

Dr. MINOT believed in accordance with the opinion of Dr. Blake, that by scraping and the application of acids the patient's life may sometimes be made tolerable for a considerable length of time.

Dr. LYMAN stated that he had seen a good many of these cases and operated on a good many. He remarked that it was singular how two cases almost precisely alike will differ in rate of growth. He had known a case to last five years, and another to grow rapidly like a cauliflower in a hot-house. He did not believe in the possibility of eradication by any means; the best chance would be by operation early in the disease either by curette or glacial acetic acid or both. Of three cases seen last winter in one the patient was so much reduced, had had so much hemorrhage, that an immediate fatal result seemed imminent, but the removal of portions and the application of tampons of sub-sulphate of iron gave such relief as to enable her to return to her home in the country where she had a very comfortable existence for a long time. Another case exhibited an immense epithelial mass, like half a potato, growing upon the posterior vaginal wall. This was not meddled with as nothing but mucous membrane was left between it and the rectum. In the third case it was also too late to do anything.

Dr. Lyman detailed cases operated upon, in every instance with partial relief. He did not think the operation stimulated the development of the disease. If the case were seen early he advised to operate as if to cure. Further, he believed that a great many of these cases had their "point de depart" in lacerated cervix, an injury which the practitioner should feel bound to operate upon if accompanied with subinvolution of uterus or much eversion of cervical mucous membrane.

Dr. BLAKE said he agreed with Dr. Lyman as to the importance of laceration of the cervix as a factor in the development of cancer. There were certainly evidences of laceration which later on developed into malignant disease, a perverted action having arisen in cells subject to causes of irritation, the disease being from a local origin thus traced.

Dr. LYMAN remarked that the operation by posterior incision and turning the prolapsed organ out from above downwards was first recommended by Craveilhier.

Recent Literature.

Columnæ Adiposæ. A newly-described structure of the cutis vera, with its pathological significance in carbuncle and other affections. By J. COLLINS WARREN, M. D., Instructor in Surgery, Harvard University, Surgeon to the Massachusetts General Hospital. Cambridge: Printed at the Riverside Press. 1881.

We are glad that Dr. Warren has seen fit to collect the papers which he has published on this interesting point of anatomy. In fact, the neat little pamphlet

before us opens with a paper that has not yet seen the light, but is to appear in Dr. Satterthwaite's long-promised Histology. As our readers know, Dr. Warren discovered in skin of various parts of the body tubular canals running in the main vertically from the subcutaneous layer to the base of the hair bulbs and containing fat. "In thin skin the canals are either so short as hardly to pass for such, or, if the hair-root is of sufficient length to extend to the bottom of the cutis, absent. A thick skin, and the existence of downy hairs are, then, the conditions necessary for the presence of this structure in its most typical form." Dr. Warren has shown that these canals can be injected from the subcutaneous surface, and that the injecting fluid will spread off from them through the cutis in various directions. We must regret that he has not endeavored to demonstrate an endothelial lining by silver nitrate.

There is no question as to the accuracy of Dr. Warren's observations; but the significance of these structures is doubtful. We were at one time half inclined to believe that they had some connection with the regeneration of the hairs, but have quite given up the theory. It seems as if their purpose is to bring the subcutaneous fat into contact with the hair bulbs, and consequently when the hairs are deep enough, or the skin thin enough, to accomplish this without them, they do not exist.

The pathological part of the work is also very interesting. It is shown that it is through these canals that the pus forms a carbuncle and the elements of morbid growths make their way to the surface.

T. D.

On Certain Conditions of Nervous Derangement, Somnambulism, Hypnotism, Hysteria, Hysteroid Affections, etc. By WILLIAM A. HAMMOND, M. D. New York: G. P. Putnam's Sons. 1881. Pp. 256.

This is a reprint, with extensive changes, of the author's *Spiritualism and Other Causes and Conditions of Nervous Derangement*, which was published in 1876. The present work can scarcely be called medical; it is rather a very interesting and instructive narration of the delusions which have attracted popular attention and gained wide belief in past ages and at the present time. The book might be supposed to have been written to disabuse the laity of certain false notions, excepting that, as the accounts given show, many physicians even need also to be enlightened. Hypnotism, somnambulism, fasting girls, ecstasy, hystero-epilepsy, stigmatization, supernatural cures, hallucinations of sight, are among the subjects considered. The stories are told well and are interesting, and may serve a good purpose in preventing some weak minded one from being deceived.

The author expresses clearly and emphatically his disbelief in so-called metallo-therapy and recounts experiments with impressionable patients showing that the results are not so much dependent upon the metal used as upon the mental state of the patient. The concluding paragraph on this is worth quoting. "We see from what has been said that there are no persons, even those whose education and practice fit them for detecting deception, who may not be readily deceived, and this by exactly the same kinds of fraud which they themselves have been most active in exposing."

In some parts, especially when considering hysteria, the author seems to have mixed up cases of insanity, raceality, and hysteria, classing them all as hysteria; also in giving a résumé of the case of Palma d'Oria (page 174), he concludes, first, that she had probably contracted syphilis; second, was strongly hysterical; third, was the subject of purpura hemorrhagica; fourth, was a most unmitigated humbug and liar. Probably the fourth conclusion would cover the whole case; if that is too harsh a judgement, then the second would be sufficient.

The author's definition of mind, which would not be generally accepted, enables him to partly explain some of the phenomena considered. He regards mind (page 243) "as a force, the result of nervous action and the elements of which are perception, intellect, the emotions and the will. Of these qualities some reside exclusively in the brain, but the others, as is clearly shown by observation and experiment, cannot be restricted to this organ, but are developed with more or less intensity by other parts of the nervous system." According to this definition the spinal cord is looked upon as in part the seat of the mind, and also the sympathetic ganglia. By this definition nothing is really gained, however, to enable us to understand the phenomena; and by speaking of mind as governing the phenomena unconsciously to the subject, when it is meant that the spinal cord or other parts of the nervous centres act automatically, the majority of people will perchance not distinguish as to which part of the mind thus acts, and may get some of the higher functions mixed up with the lower. Would it not be as well to say that the centres which take cognizance of the actions of the nervous system, and control or regulate them, are for the time being inhibited from acting and the lower centres run riot at their own free will; then somnambulism, hypnotism, etc., follow. If the control of the higher centres are only partly abolished hysteria and other allied states result.

The author seems to confound some of the events recorded in the life of Christ with the stories told of "saints" living in recent times. Having, apparently, little or no sympathy with the Christian faith he has made some allusions which will not be accepted by those who hold such a belief. Thus he refers the transfiguration of Christ to a relaxation of all the muscles of the face concerned in expression, accompanied by suffusion of the eyes and dilatation of the pupils. There are, however, only two or three such passages, and the book as a whole is a sober and rational narration, chiefly quotations, from original sources, of some of the most absurd stories and phenomena which may properly come under the various subdivisions of the book.

Constipation, Plainly Treated and Relieved Without the Use of Drugs. By JOSEPH F. EDWARDS, M. D. Philadelphia: Presley Blakiston. 1881.

A little book for non-medical people, it contains in three chapters nothing which will do any one any harm and much good advice. We hope it may reach the public for which it is designed.

—Plague is reported to have broken out again in Mesopotamia, and yellow fever is prevalent in Rio Janeiro.

Medical and Surgical Journal.

THURSDAY, MARCH 31, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY.

No. 4 PARK STREET, BOSTON, MASS.

ABDOMINAL SURGERY.

OUR readers will surely have read with much interest, in a recent number of the JOURNAL¹ an account, contributed by a correspondent from Vienna, of a case of gastric carcinoma, in which Professor Billroth successfully removed the entire diseased portion of the stomach, the patient recovering rapidly from the immediate effects of the operation. This striking case, considered in conjunction with others of similar character and import, which, during the last fifteen or twenty years, have been accumulating in the annals of medicine throughout the civilized world with constantly increasing rapidity, proclaims unequivocally that a new era of surgery has been entered upon. The peritoneal cavity and the organs therein contained are now no longer to the surgeon objects of superstitious fear,—like, as it were, an unexplored, unknown, and dreaded central Africa,—but a portion, constantly becoming more and more important, of his domain, in which his growing skill and daring may legitimately and beneficially display themselves.

The extraordinary results attained, which would doubtless have astonished and shocked our predecessors of less than half a century ago, which even now many of our most influential and authoritative contemporary colleagues are still reluctant to acquiesce in and countenance, have been due not only to increasing familiarity with the peritonæum and its contents,—familiarity in this matter bringing about its usual and proverbial result,—and to the growing audacity thereby engendered, but also, in a large measure, to the great development of the resources of antiseptic surgery, which we owe, mainly, to the creative genius and untiring perseverance of Joseph Lister. The part played by "listerism" and the benefits conferred by it have not consisted merely in the preservation of wounds, by means of carbolic acid, from putrefactive contamination, and in the successful treatment thereby of individual cases; but, by means of the antiseptic methods, widely adopted and diffused, a general prophylaxis has been effected against the various adverse and nefarious conditions summed up in the word "hospitalism," whereby even those hospital surgeons who have refused to acquiesce in the theory and practice of antiseptic surgery have unconsciously and unintentionally benefited.

Facts are more eloquent than words. We will, therefore, without further preface or apology, place

before our readers a summary of some of the most striking results recently achieved by abdominal surgery.

Ovariectomy, by virtue of the large field of experience and of eminently successful enterprise which it has afforded since 1809, when Ephraim McDowell, of Kentucky, first successfully removed an ovarian cyst by laparotomy, has unquestionably been the foundation of the important branch of operative surgery now under consideration. It is in dealing with ovarian cysts mainly, and occasionally with the various other abdominal tumors liable to be taken for them, that certain practitioners, now recognized as *abdominal surgeons*, first acquired the special experience, knowledge, and skill by which they have become able, with confidence and security, freely to incise the abdominal walls, to explore their contents, and to excise and remove morbid growths or diseased organs.

Ovariectomy, first successfully performed in this country, and subsequently styled by Piorry "*une audace Américaine*," has remained preeminently an Anglo-American procedure. The names which stand foremost in the list of surgeons who, since McDowell, have helped to establish the operation, are those of Spencer Wells, Clay, Baker Brown, Keith, Thornton, in Great Britain; of Atlee, Peaslee, Kimball, in the United States; of Péan and Koeberlé on the continent of Europe. But to no one more than to Spencer Wells belongs the honor of having raised ovariectomy, and with it abdominal surgery, to its present secure position, and of having taught the surgical world the best methods for its successful performance.

A few figures will suffice to show the great degree of success now attainable by means of this operation *in experienced hands*. Spencer Wells, only a few weeks ago, communicated to the Royal Medical and Chirurgical Society of London a paper which summarized the results of his last 200 cases, completing a series of 1000 ovariectomies performed by him from first to last. Among the 1000 patients 231 had died and 769 had recovered, the mortality, however, having steadily diminished from 34 in the first 100 to 11 in the last. The last 112 cases took place in private practice, and were all done antiseptically, the result being a mortality of 10.6 per cent. The president of the society, Mr. Erichsen, said "he would be expressing the feelings not only of the society, but of the profession and public generally, by conveying their very best thanks to the illustrious author of this great work. For no man had done such a work in surgery as to have recorded one thousand cases of any one great operation with so little mortality. Nothing can redound more to the credit, not only of Mr. Wells, but of surgery, than that such great results had been achieved by him. I have lived," continued Mr. Erichsen, "through the whole period covered by the operation, and have been present at meetings of this society when the introduction of the operation was being discussed; and I cannot but call to mind the obloquy (in which I never myself shared, for I performed the operation myself until I left it in better hands) which attended the operation and the

¹ The JOURNAL, March 10, 1881, page 238.

operator. It is something to have lived through an epoch of surgery which has seen an operation of this magnitude not only survive that obloquy, but become one of the most successful operations in surgery, when performed with sufficient care, attention to detail, and, of course, personal skill."

Among other ovariologists who have recently reported series of cases, we will only mention Mr. Knowsley Thornton, of London, who had experienced fifteen deaths in one hundred and fifty cases of complete ovariectomy, making a mortality of ten per cent., and, lastly, Dr. John Homans, of this city, whose results, lately recorded in the *JOURNAL*, were as favorable, on a comparatively small scale, as those of the most experienced operators, two deaths only having occurred in twenty-five consecutive cases of complete ovariectomy, with a mortality rate of eight per cent.

Another operation, involving laparotomy as the first step, which was a direct outgrowth from ovariectomy, is hysterectomy for the removal of fibro-cystic tumors of the uterus. Growths of this kind, by reason of their liability to simulate ovarian cysts, and on account of the supposed danger attending their removal, used to be the bane and bugbear of ovariologists. Spencer Wells formerly advised and practiced closing the abdominal incision at once, without disturbing the tumor, when it was found, upon inspection, that the surgeon had to do with a fibro-cystic myoma instead of an ovarian cyst, an intended ovariectomy being thus converted into a mere exploratory incision. In September, 1869, Péan, of Paris, notwithstanding the caution preached and practiced by Spencer Wells, successfully removed the uterus and both ovaries in a case of fibro-cystic uterine tumor, the cervix only being left to serve as a pedicle. The patient made a good recovery. The operation has been often repeated with favorable results, not only by Péan and by Koeberlé, of Strasburg, but also by Spencer Wells. The latter, in 1878, reported twenty-four cases, in which, since 1861, he had removed uterine fibroids, with or without one or both ovaries, the series including several cases of hysterectomy with removal of the fundus and body of the uterus and of both ovaries. In the twenty-four cases there were fifteen deaths, and nine recoveries, one of the latter, however, terminating fatally, from generalization of cancer, six months after the operation. In 1873 Spencer Wells expressed the opinion that "when a uterine tumor is pedunculate, or can be separated from the principal part of the uterus, or when the whole of the fundus and body of the uterus, with or without the ovaries, can be removed, leaving the cervix and its vaginal attachments uninjured, the operative question is a different one, and recent experience is leading to a more encouraging view of the surgical treatment in such cases."

A form of hysterectomy, known as the operation of Freund (of Breslau), has been resorted to with a certain degree of temporary success for the removal of cancer of the uterus. Spencer Wells, in 1878, after briefly describing this operation as a "very great improvement, which has been recently introduced by Dr. Freund, of Breslau, in the mode of removing

entirely a cancerous uterus," adds that "should it in some cases (no doubt they would be rare) be deemed desirable and justifiable to remove an entire uterus affected by cancer, this appears to me to be the best way hitherto described of doing it with a reasonable hope of success." One of the most striking extensions, however, of abdominal surgery consists in the ingenious and daring modification of the Cesarean section, known as Porro's operation, for the delivery of pregnant female dwarfs with contracted pelvic outlet. In 1876 Prof. E. Porro, of Pavia, first performed the operation which now bears his name. The results were completely successful, both mother and child surviving. The operation has been briefly described as follows in a recent valuable paper by Dr. R. P. Harris: "After the evacuation of the uterus its neck is constricted until all hemorrhage is arrested, the organ drawn out, and cut away, and the stump secured like the pedicle in ovariectomy in the lower part of the abdominal wound. The operation has in almost all instances been performed under the spray of dilute carbolic acid, and the Lister method of dressing and management strictly carried out. Drainage tubes through the Douglas cul-de-sac and the abdominal wound have also been employed, sometimes to the number of three or four, but in almost every case at least one through the cul-de-sac and vagina. The Müller modification, sometimes also called the "Rein and Müller method," is thus described by Dr. Harris: "Dr. G. Rein, of St. Petersburg, Russia, proposed, in 1877, that the uterus should be ligated to avoid all hemorrhage before it should be opened for the removal of the fetus. Müller added to this the turning out of the uterus from the abdominal cavity by a long incision, before the ligature, and then evacuating it, so as to avoid the risk of the entrance of its fluid contents into the abdomen, after which the operation is to be completed as in the Porro method." Dr. Harris, having collected a total of thirty-six cases of Porro's operation, found that in seventeen cases the mother, and in five cases the children, had died, the others, nineteen mothers and twenty-six children, surviving. In the last twenty cases of his list there were twelve recoveries, and eighteen children were delivered alive.

Yet another procedure, pertaining to abdominal surgery, which has recently been ventured upon several times with success, though quite as often attended by failure, is the removal of a kidney by nephrectomy. Mr. A. E. Barker, of London, published, a year ago, a fatal case of his own, and with it a summary of twenty-eight instances in which, for various reasons, removal of a kidney had been performed or attempted. Of the whole twenty-eight cases there were fourteen recoveries and fourteen deaths, but, excluding six instances of erroneous diagnosis, of which five terminated fatally, there were thirteen recoveries and nine deaths, two of the latter being desperate cases, in which the operation could not be carried out. In all the successful cases, recovery was complete except as regarded the possible recurrence of neoplasms. A recent number of the *Lancet* (March 5th) contains a short ac-

count of a case of nephrectomy by Mr. Morratt Baker, in which the operation, over a week after its performance, promised to prove successful. The temperature was then ranging from 98° F. to 100° F., the patient, a child, taking nourishment well, and picking up strength. "This operation," adds the *Lancet*, by way of editorial comment, "has not yet established itself as a recognized surgical procedure, and it is most important that all the cases in which it is attempted should be fully recorded."

(To be concluded.)

INCREASE IN THE DEATH-RATES OF NEW YORK DURING THE LAST FEW MONTHS.

At the last meeting of the Academy of Medicine of New York a portion of the evening was devoted to a discussion of the marked increase in the death-rate of the city during the last few months. Prof. Alfred L. Loomis believed this to be attributable to three causes: first, that New York was a malarial district; second, that the sewerage, as well as much of the plumbing, was defective; and, third, the filthy condition of the streets. Considering, as he did, that the latter was at present, perhaps, the most important element in this increase of mortality, he offered resolutions to the effect that, whereas it was the opinion of the Fellows of the New York Academy of Medicine that the uncleanly condition of the streets of the city was an efficient factor in increasing the malignancy of many diseases, and thus contributed to the present alarming death-rate, it was therefore resolved that, acting under a deep sense of their responsibilities as members of a profession whose chief duty was to check the development of disease, they earnestly warned the public against the danger of allowing this state of things to continue, and also that they were heartily in accord with the call for a citizen's meeting to be held at Cooper Union on Friday evening, March 18th, to demand relief from the legislature.

The resolutions were seconded by Prof. Austin Flint, and after remarks by him, the president, and others, were unanimously adopted. On motion of Dr. Richard H. Derby, it was resolved that the above resolutions should be authenticated by the president and secretary of the Academy, and that the president should appoint some Fellow of the Academy to present them to the meeting for street-cleaning reform, to be held at Cooper Institute, with such remarks as he might deem expedient to demonstrate that the resolutions expressed the unanimous sentiment of the Academy of Medicine, and the medical profession in general. The president then appointed Dr. Loomis to represent the Academy at the public meeting referred to.

This meeting was held at the Cooper Institute on the following evening, and proved to be a grand popular demonstration, the lead in which was taken by the most influential and distinguished citizens of New York. Chief Justice Charles P. Daly presided, and pertinent addresses were made by Dr. Loomis (on behalf of the Academy of Medicine), the Rev. Robert

Collyer, D. D., Mr. Sigismund Kaufman, Judge Brady, Mr. D. Willis James, Mr. Frederick R. Condit, Mr. Charles H. Marshall, Dr. D. B. St. John Roosa, and Mr. Joseph H. Choate. During the evening a set of resolutions, presented by Mr. Morris K. Jessup, were adopted, to the effect that those present at the meeting were convinced of the impossibility of keeping the streets of the city clean under the present system; that in their opinion there ought to be a separate department, under a single responsible head, for the purpose of cleaning the streets, and removing the ashes and garbage; that fitness, not politics, should govern the appointment of the employees of the department; that in the name of the people of the city of New York they protest against any further continuance of the present state of affairs, and appealed to the legislature for immediate and lasting relief; and that a permanent committee of twenty-one be appointed by the chairman, with power of substitution, for the purpose of obtaining the requisite legislation, who should report on the same at a future meeting, to be assembled at the call of the chairman. Before the adjournment Chief Justice Daly appointed the committee of twenty-one, in accordance with the resolutions, with Mr. D. Willis James as chairman.

MEDICAL NOTES.

— Mr. J. Lawrence Hamilton, of London, proposes to introduce an abundant supply of pure artificial vaccine lymph, produced outside the body of living man or living animal, by isolating and then breeding the vaccine organisms in suitable germ nutritive solutions which have been previously deprived of all septic and other noxious germs. The special precautions which Mr. Hamilton considers necessary to secure success in breeding the artificial vaccine lymph, as well as the results of therewith inoculating men and animals, will be published at a future date.

— From the latest official data now furnished by the *Medical Register* up to date, it appears that the whole number of persons now on the *Medical Register* as being legally qualified to practice for 1881 is 22,936. Of these there are in England 15,918, in Scotland 3,451, in Ireland 3,564; so that it appears that 69 per cent. of the whole number of British practitioners are registered in England, 15 per cent. in Scotland, and 15.6 per cent. in Ireland. These numbers have remained pretty invariable since the *Medical Register* was first begun in 1858; the average percentage throughout that time being 69.2 in England, 14.6 in Scotland, 16.2 in Ireland. A slight increase appears in the number of practitioners during the last five years; the total number of medical practitioners for 1877 having been 22,713, while it is now 22,936. — *Cincinnati Lan. and Clin.*

— Edinburgh has a Society for the Relief of Persons laboring under Incurable Diseases. It has a roll of over two hundred pensioners.

— At the last meeting of the New England Psychological Association, Dr. Calvin S. May was unanimously expelled.

— According to the *London Medical Journal* several members of the profession in England, possibly with the view of rubbing up their knowledge of foreign tongues, have adopted the practice of addressing the secretaries of the International Medical Congress in various languages. One gentleman, who has had occasion to write three letters, has availed himself of the opportunity thus afforded to show his acquaintance with Italian, German, and French. This system is not without its advantages, as it has benefited a worthy interpreter, who has been permanently engaged to meet this unforeseen emergency.

— Miss Isabella Bird, in her recent charming work, *Unbeaten Tracks in Japan*, describes a visit to a native hospital at Kubota, under the charge of Dr. Kayobashi, who "is fresh from the medical college at Tôkiyô, and has introduced the antiseptic treatment with great success." Miss Bird says: "the odor of carbolic acid pervaded the whole hospital, and there were sprays enough to satisfy Mr. Lister! At the request of Dr. Kayobashi I saw the dressing of some very severe wounds carefully performed with carbolized gauze, under spray of carbolic acid, the fingers of the surgeons and the instruments used being all carefully bathed in the disinfectant." — *Medical News and Abstracts*.

— The question has been raised in England, whether when a workingman is isolated because of contagious disease in his family, compensation from public funds should be allowed him for the loss of his labor. The argument made is as follows:—

"This man is required by law to absent himself from his vocation, and thereby prevented from earning money, in order that he shall not spread a contagious disease, and this at a time when his normal expenditure is heightened by the necessities of sickness. The law offers him no compensation for this sacrifice, and the workingman must, under such circumstances, accept parish relief or starve. A sanitary authority, drawing its funds from public rates, should have the power of appropriating such funds for the purpose of supporting persons whom the exigencies of public health require to be isolated from their work, and thus remedy the incongruity of victimizing a defenseless artisan for the public good."

It appears to us that the social standing or poverty of the person to be isolated has nothing to do with the equity of the case. If it is just that the hod-carrier should be compensated for the loss of his time, it is just that the lawyer or the merchant should also be compensated. As a matter of fact it does not appear just that either should be compensated from the public funds any more than he should be compensated for his fees to the physician, or for the wages of his nurse. — *Sanitary Engineer*.

— At a dinner of the Boston Druggists' Association, on the evening of February 22d, in the course of an address by Mr. Theodore Metcalf upon the condition of the business as early as 1837, he concludes his remarks by speaking of the physicians then in practice here, making the following personal allusions:—

* Of the older physicians to whom I had letters,

upon coming to Boston, all are gone, save one; some of them succeeded by sons and grandsons, now as eminent as they then were. No shape of man in that array graces the sunshine of to-day, save one, and of him I will speak, if you will permit me, in the words of another:—

"The monumental pomp of age
Is with the goodly personage,
A stature undepressed in size,
Scarce bent, which rather seems to rise
In open victory o'er the weight
Of ninety years, to loftier height,
Magnific limbs of withered state,
A form to love and venerate."

Those who knew him will recognize in these lines the image of the venerable Dr. Edward Reynolds, my earliest professional friend in Boston. As he has long been out of active practice, I the more readily pay to him this tribute of respect:—

"Let others hail the rising sun,
I bow to him whose course is run."

— A recent judicial decision in Maine declares that a burial ground which does not affect the physical health of the occupants of a dwelling-house near which it is located, nor their olfactories by any effluvia from the graves, is not in law a nuisance. The human contents of graves cannot offend the senses in a legal point of view. To become a nuisance the graves, or their contents, must be such in their effect as naturally to interfere with the ordinary comfort, physically, of human existence, and the inconvenience must be something more than to fancy, delicacy, or fastidiousness.

— The Women's State Christian Temperance Union is circulating among physicians a reprint of a paper which was read before the North of England Branch of the British Medical Association, entitled *The Power Medical Men Possess of Aiding in Temperance Reform*.

NEW YORK.

— Nearly forty cases of typhus fever were reported at the office of the Board of Health during the week ending March 19th. Three cases were reported from the German Hospital, six from the Charity Hospital, Blackwell's Island, and two from a house in West Twenty-Seventh Street. All the others were traced to the Shiloh Lodging-House, at the corner of Prince and Marion Streets. This building is an old church, formerly occupied by a congregation of negroes, but which for many years remained deserted, and is now in a very dilapidated condition. Two or three years ago it was fitted up as a lodging-house for tramps and other imperunious members of the community, who, by the payment of eight cents, can secure a bunk for the night, and a breakfast, consisting of a roll and a cup of coffee, in the morning, while those who are too poor to afford this expenditure are permitted to pay for their lodging and breakfast by splitting up a certain quantity of wood. Almost every night during the past winter this place has been crowded to its utmost capacity. The building is now thoroughly fumigated every day, and an inspector from the health department has been stationed at the door to examine each lodger before he enters. It is probable that it

will not be closed at present, as that would only tend to spread the disease to other lodging-houses of the same class. The present is the most serious outbreak of typhus that has occurred in New York for quite a number of years, but the Board of Health are using every means at their disposal to prevent the spread of the disease. All last year there were but two cases reported, and the highest number of cases noted in any one week during the last ten years was in October, 1871, when nine were reported in a single week.

—A few days ago, about eight o'clock in the morning, the people on upper Broadway were startled by beholding a negro running down the street stark naked, and pursued by a large crowd of men and boys shouting "small-pox!" He was quickly captured, however, by two policemen, who threw a horse-blanket around him, and took him to a neighboring station-house, whence he was presently conveyed to the reception hospital, at the foot of East Sixteenth Street. It seems that the man had gone to bed not feeling well the evening before, and that during the night confluent small-pox had developed itself. In the morning, in the violent delirium peculiar to the disease, he had sprung out of bed, torn off his night-shirt, and rushed into the street naked.

—The College of Pharmacy of the city of New York held its fifty-first annual commencement at Chickering Hall, on the evening of March 22d. Addresses were made by Ewen McIntyre, the president, and by Douglas Campbell, and the valedictory was delivered by Eugene L. Fridenburg. Three scholarship prizes were awarded, and two special prizes for essays on Botany and Pharmacy, respectively. There were sixty-five graduates.

—On the same evening a meeting of the New York Cremation Society was held in one of the rooms of the Cooper Institute, when a paper, entitled *The Disposal of the Dead—a Plea for Cremation*, was read by Dr. Edward J. Birmingham, editor of the *Hospital Gazette*. In the course of it he spoke of the rapid extension of New York towards Woodlawn Cemetery, and the proximity of the thickly settled portions of Brooklyn to Greenwood, and claimed that the sanitary necessity for cremation formed the strongest argument for its general adoption.

—Mr. A. B. Stone has just purchased for twenty thousand dollars a handsome site at Bath, Long Island, called Bath Park, for the Children's Aid Society. It contains four and a quarter acres, with trees, pavilions, bath-houses, and many conveniences for a sanatorium, and has a frontage of about four hundred and fifty feet on the sea, at a point where the bathing is peculiarly safe. The new summer home will be the resort of the poor children of the tenement houses during the hot weather.

—The bill requiring all the plumbers of New York and Brooklyn to have their names registered, and also giving the boards of health of the two cities supervision over all new plumbing, has been ordered to a third reading by the Assembly at Albany. This bill is the one drawn up by the New York Sanitary Reform Society.

Miscellany.

SANITARY LEGISLATION.

THE following amendments to the General Statutes of Massachusetts relating to boards of health are under consideration by the legislature, and are likely soon to become law:—

Chapter one hundred and thirty-three of the Acts of eighteen hundred and seventy-seven is hereby amended by striking out from the fifth section the last five words, as follows: "where such connection is made," and inserting in place thereof the words, "where a public sewer abuts the estate to be drained."

The Committee on Public Health, to whom was referred the Order relative to the expediency of further legislation in regard to Boards of Health in towns, and the Order relative to the expediency of further legislation for the Protection of the Children in the Public Schools against Contagious Diseases, report the accompanying Bill.

Section one of chapter twenty-six of the General Statutes is hereby amended so as to read as follows:

"Section 1. In each of the several towns of this commonwealth, the board of selectmen shall, in the month of January in the year eighteen hundred and eighty-two, appoint two persons, neither of whom shall be a member of the board of selectmen, and one of whom shall be a physician (provided there be a resident physician), who, together with the chairman of the board of selectmen, shall constitute the board of health of each town.

"The board so constituted shall enter upon its duties on the first Monday of February then next succeeding. The terms of office of the two appointed members shall be so arranged at the time of their appointment that the term of one shall expire on the first Monday in February in each year after the year eighteen hundred and eighty-two.

"In each of said towns, said boards of health shall annually, in the month of January, present to the State Board of Health, Lunacy, and Charity, a report made up to and including the thirty-first day of the preceding December, upon the sanitary condition of the town during the year."

THE CATGUT LIGATURE.

FROM the extremely interesting address on the above subject by Professor Lister, delivered before the Clinical Society of London, January 28th, we quote his description of the proper preparation of catgut ligatures. After speaking of the inconvenience of the extremely long period which the old method requires, he gives as follows the conditions for a perfectly satisfactory state of the catgut for surgical purposes. "In the first place I have spoken of a short period of preparation. This is very desirable. Then it is essential that the catgut should have proper strength, so as to bear any reasonable strain that the human hands can put upon it, in the thicker forms, as when used, for instance, in such cases as the circumferential ligature of the thyroid vessels in the removal of a goitre, or for securing the pedicle in ovariectomy. And it is not sufficient that it should be strong to start with; it is easy to get catgut strong in the dry state; it is necessary that it should be strong after steeping in blood-serum for a while. Take, for example, the case of a

tumor of the thyroid. I employed six ligatures, and in a former case I thought it prudent to pass as many as eight, but it is not convenient to tie each of these ligatures as soon as it is passed, and the process of passing takes a considerable time. Now it would be a very sad thing if the residence of the catgut among the tissues soaked with serum for a few minutes, or even a quarter of an hour, should render the catgut so soft that it should give way when we put the strain of the hands upon it. That, then, is another point essential, if the material is to be useful for all the purposes for which it is desired. Then, again, it is necessary that a knot tied upon it should hold with absolute security, not merely in the first instance, but after soaking for an unlimited time in blood-serum. It is further needful that it should not be too rigid, for, as we shall see immediately, it is possible for catgut to be over-prepared, in which case it may remain almost like a piece of wire among the tissues, and ultimately, perhaps, come away by suppuration in consequence of the mechanical irritation which it produces. But while the animal juices must be able to soften it sufficiently to render it mechanically unirritating, yet, on the other hand, it will not do for it to be too rapidly disposed of by absorption. If it is to do duty for the ligature of an artery in its continuity in the immediate vicinity of some large branch, it must remain for a considerable time of good strength, unabsorbed, and, when it is at length absorbed, it is desirable that it should be removed in such a manner that, while it is reduced in thickness, it should still, as long as any of it remains, retain its tenacity.

"Now, these are a series of conditions which, I assure you, it is not easy to fulfill completely. I have in various experiments complied with some of them easily enough, but failed in others. Sometimes I have succeeded with all but one, and one has baffled me. I have tried various materials, as you will naturally suppose."

Professor Lister gave in detail many of his experiments on the subject, and then described his present method.

"I dissolve one part of chromic acid in four thousand parts of distilled water, and add to the solution two hundred parts of pure carbolic acid or absolute phenol. In other words, I use a one to twenty watery solution of carbolic acid, only that the carbolic acid is dissolved, not in pure water, but in an exceedingly dilute solution of chromic acid. But minute as is the quantity of the chromic acid, it exerts, when in conjunction with carbolic acid, a most powerful effect upon the gut. The first effect of the addition of the carbolic acid to the chromic solution is to change its pale yellow color to a rich golden tint. But if the liquid is allowed to stand without the introduction of the catgut it changes, in the course of a few hours to a dingy reddish brown, in consequence of some mutual reaction of the two acids, and a considerable amount of reddish-gray precipitate is formed. If, however, catgut about equal in weight to the carbolic acid is added as soon as the ingredients are mixed, the liquid retains its brightness, and the only change observed is a gradual diminution of the depth of the yellow color, the precipitate which, I presume, still occurs, taking place into the substance of the catgut. As soon, therefore, as the preparing liquid has been made, catgut equal in weight to the phenol is introduced into it. If you have too large a proportion of catgut it will not be sufficiently prepared, if you have too small a quantity,

it may run the risk of being over-prepared. At the end of forty-eight hours the chromic element of the liquid has nearly spent itself, and precipitation is complete. The catgut is then taken out of the solution and dried, and, when dry, placed in one to five carbolic oil; it is then fit for use. I have here a sample of catgut prepared by this method. Although it has been steeped in warm blood-serum since this morning at eleven o'clock, it is still translucent and firm without being rigid, and a reef-knot tied upon it holds with the most perfect security.

"The strength of the catgut depends upon different circumstances. In the first place, sheep differ as to the strength of their intestines, and the catgut maker, if he understands his business, will insist upon having his raw material of a proper kind. In the next place, the intestines must not be allowed to putrefy, they must be used when quite fresh. For these things you must, of course, rely upon the maker of the catgut. In the next place, the preparing liquid causes a certain amount of softening of the catgut, and if it is introduced in loose hanks this will tend to produce a little uncoiling of the twisted cord, and a still greater degree of uncoiling will take place during drying. It is of very great importance that this should not occur, because it involves weakening of the thread, and that in different degrees in different parts, and this may lead to the gut giving way when you subject it to a strain. The catgut, then, should be prepared on the stretch, both when it is put to soak and when it is put to dry.

"I need not enter into the mode in which this can be done by the manufacturer. I may only say this, that the surgeon who wishes to prepare it himself may do it in different ways. For instance, he may take two large test tubes, one a little larger than the other, and he may wind the catgut on the smaller tube, fixing one end by sealing-wax, winding it round, and then bringing it up again, and fixing the other end with sealing-wax at a higher level than the liquid will reach, putting sufficient liquid into the larger test tube, and introducing the smaller test tube with the catgut wound round it, with a little shot to keep it down in the liquid. After forty-eight hours he takes out the smaller test tube, and leaves it till the catgut is completely dry. I merely mention this as an illustration, and also as furnishing a hint to some surgeons in private practice who may desire to prepare the catgut themselves. Or a couple of gallipots, one larger than the other, will do just as well. But, as I have already said, the principal uncoiling takes place during drying, and for all ordinary purposes a sufficiently good article is got by putting the catgut loose into the liquid, and making it dry on the stretch by tying the ends of each hank to two fixed points in a room.

"In the dry state, catgut prepared by this method is as strong as need be. As to strength in the condition after steeping in blood-serum, I confess it is only this very day that I have obtained evidence that catgut thus prepared is really all that we can desire in that respect. The catgut of the hank from which this specimen was taken measured, in the dry state, two and two thirds hundredths of an inch in diameter, and broke at thirteen pounds six ounces. I have found, by experiment, that ten pounds is the utmost strain that my arms are able to put upon a cord. Thirteen pounds six ounces, then, is amply sufficient, while, at the same time, the catgut is not at all too large for going into the eye of an aneurism needle."

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 19, 1881.

Deaths reported 2844; 1087 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 581, lung diseases 425, consumption 417, diphtheria and croup 190, scarlet fever 105, small-pox 62, cerebro-spinal meningitis 57, diarrheal diseases 42, typhoid fever 40, malarial fevers 24, measles 21, erysipelas 20, whooping-cough 15, puerperal fever five. From *cerebro-spinal meningitis*, New York 15, St. Louis 14, New Orleans eight, Chicago seven, Philadelphia three, Brooklyn two, Cincinnati, Milwaukee, Lynn, Newton, Northampton, Attleborough, Quincy, and Milford one. From *diarrheal diseases*, New York 10, New Orleans five, Brooklyn and Baltimore four, District of Columbia three, Philadelphia, Chicago, Boston, and St. Louis two, Cincinnati, Pittsburgh, Milwaukee, New Haven, Lowell, Cambridge, Brockton, and Quincy one. From *typhoid fever*, Philadelphia nine, New York six, Lowell four, Chicago and St. Louis three, Brooklyn, Pittsburgh, and Lawrence two, Boston, Baltimore, Cincinnati, District of Columbia, Buffalo, Milwaukee, Nashville, Attleborough, and Amherst one. From *malarial fevers*, New York and St. Louis eight, Brooklyn four, Chicago and Baltimore two. From *measles*, Boston eight, New York five, Philadelphia and Nashville two, Chicago, St. Louis, Pittsfield, and Brookline one. From *erysipelas*, New York five, Philadelphia, Baltimore, and Cincinnati two, Brooklyn, Chicago, Boston, St. Louis, Pittsburgh, Providence, Cambridge, Lawrence, and Haverhill one. From *whooping-cough*, Philadelphia four, District of Columbia two, New York, Brooklyn, Chicago, St. Louis, Cincinnati, Providence, Cambridge, Springfield, and Somerville one. From *puerperal fever*, St. Louis, two, New Haven, Lowell, and Fall River one.

Nine cases of small-pox were reported in Brooklyn, 16 in Chicago, and three in Pittsburgh; diphtheria 46, scarlet fever 11, in Boston; scarlet fever 24, diphtheria seven, in Milwaukee.

In 46 cities and towns of Massachusetts, with a population of 1,141,363 (population of the State 1,783,086), the total death-rate for the week was 20.19, against 20.44 and 21.99 for the previous two weeks.

For the week ending February 26th, in 149 German cities and towns, with an estimated population of 7,880,919, the death-rate was 25.3. Deaths reported 3837; 1771 under five; pulmonary consumption 543, acute diseases of the respiratory organs 411, croup and diphtheria 149, scarlet fever 87, measles and röteln 50, whooping-cough 47, typhoid fever 45, puerperal fever 21, small-pox (Munich, Regensburg, Aachen five) seven. The death-rates ranged from 16.7 in Bremen to 38.4 in Strasburg; Königsberg 35.4; Breslau 32.6; Munich 37.1; Dresden 26.4; Berlin 23.9; Leipzig 22; Hamburg 23.3; Hanover 17.8; Cologne 25.9; Frankfurt 20.9.

For the week ending March 5th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 23. Deaths reported 3355; acute diseases of the respiratory organs 419, whooping-cough 82, scarlet fever 57, small-pox (London 52) 53, diarrhoea 34, measles 28, fever 26, diphtheria 16. The death-rates ranged from 17.2 in Brighton to 26.5 in Liverpool; Bristol 19.5; Birmingham 21.1; Leeds 21.4; Sheffield 22; London 23; Manchester 25.2. In Edinburgh 22.3; Glasgow 22.8; Dublin 36.

In the 20 chief towns in Switzerland, for the week ending March 5th, actual population according to census just published 548,301, there were 41 deaths from acute diseases of the respiratory organs, diphtheria and croup 17, diarrheal diseases 17, typhoid fever seven, measles four, small-pox four, whooping-cough, puerperal fever three. Death-rate of Geneva 26.6, Zurich 31.8, Basle 30.9, Berne 45.7.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 19, 1881, TO MARCH 25, 1881.

GIBSON, J. R., major and surgeon. Relieved from duty at Fort McHenry, Md., and to report to the commanding officer United States Barracks, Washington, D. C., for duty as post surgeon. S. O. 52, Department of the East, March 22, 1881.

MEACHAM, F., captain and assistant surgeon. To report for duty to the commanding officer, Fort Hamilton, New York Harbor. S. O. 52, C. S., Department of the East.

REED, W., captain and assistant surgeon. Awaiting orders at Fort McHenry, Md., to report to the commanding officer of that post for duty. S. O. 52, C. S., Department of the East.

PORTER, J. Y., captain and assistant surgeon. Granted leave of absence for one month, to take effect from 6th proximo. S. O. 28, Department of the South, March 22, 1881.

SHUE, E. D., first lieutenant and assistant surgeon. When relieved at Fort Grant by Assistant Surgeon J. B. Girard, to report in person to the commanding officer Camp Thomas, A. T., for duty. S. O. 27, Department of Arizona, March 8, 1881.

ARTHUR, WILLIAM H., first lieutenant and assistant surgeon (recently appointed). To report in person to the commanding general, Department of the Platte, for assignment to duty. S. O. 62, A. G. O., March 17, 1881.

BESUNELL, GEORGE E., first lieutenant and assistant surgeon (recently appointed). To report in person to the commanding general, Department of Dakota, for assignment to duty. S. O. 62, C. S., A. G. O.

BIRMINGHAM, H. P., first lieutenant and assistant surgeon (recently appointed). To report in person to the commanding general, Department of the Missouri, for assignment to duty. S. O. 62, C. S., A. G. O.

WYLLIE, M. C., first lieutenant and assistant surgeon (recently appointed). To report in person to the commanding general, Department of Dakota, for assignment to duty. S. O. 62, C. S., A. G. O.

KING, J. H. T., captain and assistant surgeon. The leave of absence granted him in S. O. 253, November 29, 1880, from A. G. O., is extended to June 30, 1881, and his resignation accepted by the President of the United States, to take effect June 30, 1881. S. O. 65, A. G. O., March 21, 1881.

Lectures.

CEREBRAL LOCALIZATION.

BY N. N. MUDD, M. D., ST. LOUIS.

THE brain is an organ of the mind, each mental operation prompts its functional activity. As a condition essential to nervous activity in all the higher animals we recognize the existence of afferent sensory tracts, carrying sensations to a ganglionic centre, composed of cells, and efferent motor tracts conveying motor impulses.

These fundamental facts of anatomy, as well as all analogy, point to the conclusion that "identical mental operations always are associated with functional activity of identical tracts of nerve fibres and cells in the brain and its dependencies."

These tracts and these nerve cells or ganglia are localized, circumscribed, and their functional activity is always the same. It is no proof that these tracts are not well defined that we fail to trace them through the intricate anatomy of the cerebral hemispheres, nor does it seem to me that because there may be an overlapping of the different perceptive and volitional centres that this is an argument against localization of functions. Again, in such an intricate structure as the brain there must be a degree of interdependence of its various parts. It is not complete and perfect in any of its divisions, except as it is perfect as a composite whole. This must be conceded, but should not be allowed to militate against the truth of Ferrier's doctrines.

The doctrines of cerebral localization are now awakening world-wide interest among scientific men. Experimental physiology and keen and accurate observations at the bedside are confirming many of the theories advanced by the exponents of, and the enthusiastic workers in, this department, in their endeavor to localize cerebral functions.

[At this point the lecturer exhibited the accompanying chart, taken from Ferrier, on which he pointed out the different portions of the cerebro-spinal axis, and explained their functions.]

The nervous system in all the higher animals is composed of afferent sensory fibres, ganglionic centres, and efferent motor tracts, together with an intermediate basis substance, where these cell units are aggregated.

In this chart (pointing to the accompanying diagram) the dark circles indicate the sensory centres, the arrows indicating the course of the ingoing currents. The motor or volitional ganglia are those which you see marked with a simple ring or circle. The circles represent the encephalic and the spinal centres, A A' represent the reflex or excito-motor centres of the spinal cord. These may act quite independently of the higher centres of the encephalon. B B' indicate the region of more complex reflex action, such action as we have controlling the respiration, the circulation, and the vaso-motor nerves. Passing still higher we find in C C', which are directly connected with D, the cerebellum, the mesocephalic centres, where, as it is well known, we locate the complex forms of activity, such as locomotion, emotional expression, and equilibrium.

Just here it is well to recall a fact which is well established by experiments upon inferior animals, that the independence of the mesocephalic ganglia and the

cerebellum is in inverse ratio to the development of the cerebral hemispheres. The diagram will indicate how we may cut off the cerebellum without disturbing the functional activity of the mesencephalic ganglia, and without affecting conscious sensation and voluntary motion. The localization of these different functions has been long well known, and is established with more or less precision.

In 1870 Fritsch and Hitzig established by a series of experiments the fact that the direct application of the faradic current to the surface of the hemispheres in certain well defined regions caused movements. This fact, as also the more important one that the irritation of certain circumscribed areas was always associated with definite muscular contraction, is well proven. It was, before this, generally believed that the cerebral hemispheres acted as a unit, as a composite mass, which represented the site of conscious sensation and volition, but it was *not* believed that definite functions could be ascribed to different regions of the cerebrum.

[Referring again to the chart.] E E' represent the basal ganglia, E corresponding to the corpora striata,

while E' represents the sensory ganglia, the thalamus optici. In these basal ganglia we have differentiated the various functions of the cerebral lobes, G F' and F; and in the convolutions of the different lobes we have localized the different conscious cerebral actions.

Can we now assign to certain parts of the cerebrum determined functions? Ferrier asserts positively that definite areas of the cerebral hemispheres have certain well defined functions, and supports his theory by many facts deduced from experiments upon the monkey, in which he irritated different portions of the brain by the use of the faradic current. The definite muscular activity resulting from this irritation cannot come from its conduction to the basal ganglia, for when we apply the current directly to the basal ganglia there is a general muscular spasm, and not the definite, localized, circumscribed activity that we get from irritation of particular convolutions of the cere-

¹ Read before the St. Louis Medical Society, January 15, 1881.

brum. Clinical observation also offers many confirmatory evidences of the localization of functions in the cerebral convolutions.

Let us look for a moment at the anatomy of the cerebral hemispheres, and see whether we find in the normal structure of the part any reason to believe in the localization of cerebral functions in the convolutions. The gray matter of the hemispheres is distributed in two different and distinct regions. The central ganglionic masses composed of the thalami optici and corpora striata, forming the basal ganglia, and the laminae of gray substance everywhere present on the surface of the convolutions, forming the second region.

Charcot, in his work, *Localization in Diseases of the Brain*, describes the central ganglia and their relations so well, that I present a chart copied from his work. [At this point the lecturer exhibited a diagram of a vertical transverse section of the brain.]

The white band running upward through the central ganglia Charcot terms the internal capsule. It is composed almost entirely of white connecting fibres, which pass between the crura of the brain and the convolutions. Above and to the inner side of the internal capsule we have the gray nucleus of the thalamus opticus. Below and to the outer side of the internal capsule we have the lenticular nucleus of the striated body.

Connecting the cerebral mass and the cerebral peduncles with the convolutions we have, "first, radiating fasciculi of the thalami optici. Second, radiating fasciculi of the corpora striata. Third, radiating fasciculi of the lenticular ganglia. Fourth, the direct fasciculi which go to the foot of the peduncle without stopping in the gray central ganglia." These different fibres may be recognized in sections of the internal capsule.

Perhaps the most authentic and best established localized functions in the cerebral cortex are in the psycho-motor zone of Ferrier, which is located around the fissure of Rolando. About this fissure is an arrangement of the gray laminae which is peculiar to this region, and is confirmatory of the experiments of Ferrier. Here are found pyramidal motor cells, giant cells, which resemble very much the multipolar motor cells of the anterior cornua of the spinal cord. These cells are very largely developed in regions in which Ferrier, by experimental physiology, has located motor activity. We find upon the occipital and sphenoidal lobes, in which sensory functions have been located, granular cells, very different from those of the motor zone. Thus histological researches confirm the doctrines of cerebral localization.

Before considering the anatomy of the circulation of the brain we will look a moment at the differences in character of the diseases of the spinal cord and of the brain. The so-called "systemic lesions" of the cord are well understood and distinctly circumscribed. They may involve also the rachidean bulb, but above this point we find an entire change in the character of the disease. In the brain the circulation is the key to the pathological changes. Circumscribed diseases of the brain are generally dependent on either thrombosis, embolism, hemorrhage, or changed nutrition produced by disturbed vascular supply. These sources of disease are active also in the intermediate structures formed by the medulla and the pons Varolii, but we do not find any such conditions pertaining to disease of the cord proper.

The circulation of the cerebral hemispheres, the

manner of the distribution of the arteries, the isolation of the central ganglia from the cortical layer, indicate independent activity. According to Duret and Heubner, — from whom much of the precise knowledge of recent date concerning the circulation of the brain is derived. — there are two systems of vessels, the central and the cortical; the central system being derived very largely from the sylvian or middle cerebral artery, the anterior cerebral supplying only a small portion of the caudate ganglion, while the posterior cerebral supplies a part of the thalami optici. From the same trunks, but farther out, are derived the vessels for the cortical system.

These two systems are entirely independent, and have no manner of communication in their peripheral distribution. The circulation of the central ganglia is entirely distinct and separate from that of the cortical portion of the brain. There is an intermediate territory between the two which is poorly nourished, and which is frequently the seat of senile softening.

The arteries of the central system are given off at right angles to the trunks of the sylvian arteries as they run along the inferior surface of the brain, and may be divided into two sets. First, those supplying the anterior portion of the internal capsule; second, those supplying the posterior portion of the internal capsule. These branches are distributed in the central mass, and have but slight if any anastomoses with each other.

The cortical branches of the sylvian artery pass out and break up into primary and secondary branches, which ramify in the pia mater and run parallel with the cerebral convolutions. From these ramifications are derived the nutrient arteries, which penetrate the gray cortex and pass into the convolutions, not only from the cortex but from the sides of the convolutions, and converge towards a central point.

For the present we may say that our ability to discriminate in the regional diagnosis of lesions of the central mass consists in our ability to recognize disturbances of the internal capsule. We can often determine whether the anterior or posterior portion of the capsule is involved in disease, for in the one we may have hemianesthesia and in the other only hemiplegia.

In cerebral topography there are some well-marked fundamental fissures and convolutions; for instance, we have the fissure of Sylvius with its anterior and vertical or posterior arms, dividing the anterior from the middle lobe of the brain. Running vertically upwards from near the anterior portion of the horizontal limb of the sylvian fissure is the fissure of Rolando, which passes upwards and inwards to the longitudinal fissure. Upon either side of this fissure is situated the motor zone of the cerebral hemisphere, composed in front of the ascending frontal convolution and the posterior part of the first frontal convolution, and behind of the ascending parietal convolution, and near the median line a part of the parieto-occipital lobe.

Extending forward from the ascending frontal convolution are two fissures nearly parallel with the longitudinal fissure, which divide the frontal lobe into the first, second, and third frontal convolutions. The frontal lobes are the seat of the intellect, the posterior inferior part of the third frontal being the centre of speech.

In the parietal lobe is the intra-parietal sulcus, below which is the supra-marginal convolution and the angular gyrus in which is located the centre of sight.

Below the fissure of Sylvius the temporo-sphenoidal

sulcus separates the superior from the middle sphenoidal convolution. In the superior temporo-sphenoidal convolution is located the centre of hearing, while in the middle and inferior temporo-sphenoidal are centres of smell and taste.

If we can ascribe to the convolutions in the occipital lobes special functions it is in connection with the functions of organic life; the sense of well or ill being, as evidenced in nutrition or in the condition of the gastro-intestinal canal.

Looking on the inferior surface of the cerebrum we see the dentate fissure, close to the posterior border of the corpus callosum, and continuous with this fissure posteriorly we have the calcarine sulcus. External to this, between it and the collateral fissure, is a convolution extending toward the anterior part of the middle lobe, the uncinate convolution, or the hippocampal region, in which is located tactile sensation.

Dividing the brain at the longitudinal fissure into two lateral halves, upon the median surface is observed a fissure which runs parallel with the anterior portion of the corpus callosum, called callosa marginal. Above this is the frontal lobe, below the gyrus fornicatus. Between the parieto-occipital fissure and the posterior part of the callosa marginal sulcus we have the præcuneus or quadrilateral lobe.

If we are to make use of the deductions of experimental physiology in our practical work as physicians, it will be after we have learned to locate exactly and describe with anatomical precision the lesions that we find in post-mortem examinations. Clinical examinations made during the progress of disease without a knowledge of the facts of localization as taught by experimental physiology will not be made with sufficient accuracy to prove whether the lesions found on post-mortem examinations are confirmatory or not of the doctrines of cerebral localization.

The precise relation of these fissures and convolutions to the prominent points of the skull is of clinical importance. The coronal and lambdoid sutures divide the skull into the frontal, parietal, and occipital regions. The frontal region is subdivided by two lines, one of them corresponding with the anterior portion of the temporal arch, the other midway between this and the median line, forming the supra, mid, and infra frontal regions.

The parietal region is divided by a line running vertically through the parietal eminence into the anterior and posterior parietal regions. Each one of these is subdivided by a line drawn along the temporal arch into a superior and inferior anterior or posterior parietal region.

If I draw a line through the anterior parietal region from the sagittal suture to the point of junction of the squamo-parietal and the sphenoparietal sutures, I shall outline very clearly the position of the fissure of Rolando, and about this we find the psycho-motor zone, which is located almost entirely in the anterior parietal region.

The posterior parietal lobe, in which is located the centre of motion of the leg and foot, as in locomotion, extends into the upper portion of the post-parietal region. In cranial topography the cortical centre of sight is about the parietal eminence, hearing in the lower anterior parietal region, smell and taste in the temporo-sphenoidal region, while the tactile sense is more deeply placed on the inferior surface of the cerebrum.

In 1879 I had an opportunity of observing a case in

which the psycho-motor zone was involved, and which gave evidence of irritability of the cerebral cortex, the irritability being evinced in convulsive movements of the limbs. The man received a blow upon the head which contused the bone and induced inflammatory softening of the osseous tissue, but there was no inflammation of the membranes, neither was there any pressure upon the brain. The injury was inflicted just above the parietal eminence of the left side, and about one and a quarter inches from the middle line. Fifteen days after the injury the man noticed a twitching of his right leg, which was involuntary, and which increased from hour to hour until he was seized with epileptic convulsions.

The site of injury corresponded exactly with the situation of the convolution, as located by Ferrier, which is active in producing motions of the leg. The injured bone was removed, the membranes were found healthy, and the convulsive movements ceased.

Dr. Hall, of the northern part of the city, had under observation a man aged forty-two, shot accidentally December 26, 1880. The ball entered the forehead two inches above the junction of the eyebrows; passing through the skull, it passed through the posterior portion of the first frontal convolution and impinged on the skull about one and a half inches in front of the occipital bone to the right of the median line. From this point it was deflected downwards toward the superior curved line of the occiput, passing through the occipital lobe. As you will observe, the track of the ball injured first the convolution active in controlling the lateral movements of the head and the elevation of the eyelids; it then passed through the greater portion of the motor zone of the arm, hand, and leg, left untouched the convolution presiding over the muscles of the face, angle of the mouth, of the lips, and tongue.

The symptoms in this case indicated very nearly the track of the ball, for during life he was unable to elevate perfectly the eyelids, he had complete hemiplegia of the left side, but could talk; there was but little distortion of the muscles of the face, the lips responded to the stimulus of the cup placed to them, and he drank, although he did not complain of hunger nor thirst.

A peculiar symptom of this case was that upon touching the paralyzed side he recognized the touch in every instance; but instead of referring it to the point touched he invariably referred it to the corresponding point on the opposite side of the body. If symmetrical points were touched at the same moment he recognized only the touch upon the sound side. It will be observed in the description of this injury to the brain that the hippocampal region, the site of tactile sensation, was undisturbed.

— The *British Medical Journal* reports the death of a child, aged seven months, from the effects of a needle, which had found its way into the body either by swallowing or from without. About a fortnight ago the infant was seized with very peculiar and unexplainable symptoms of illness, the only outward indications being irritation and a hardness on the left side of the body. These symptoms increased, and the child died. A post-mortem examination showed that a common sewing-needle had pierced the pericardium, and imbedded itself in the lower region of the heart.

PODODYNIA: ITS CAUSES AND SIGNIFICANCE.¹

BY T. B. CURTIS, M. D.

THE word *pododynia*, or *podalgia*, is here used, for the sake of brevity, to designate certain painful affections of the feet, in which pain, spontaneous or provoked by contact and pressure, exists independently of any physical signs, visible or tangible, of local organic disease of the part, whether inflammatory or traumatic. A puzzling and refractory case, encountered in private practice a few years ago, furnished the occasion and incentive for studying the different varieties of painful affections of the feet, in which mere *pain*, apparently independent of any gross lesion, constituted the main, or only, symptom complained of by the patient. I was thus led to rehearse and investigate the numerous etiological conditions in which pododynia, as above defined, is liable to occur; and the following short account of what was to be found in medical literature touching this comparatively unimportant topic, represents merely a contribution to the elucidation of the semeiology of pain in the foot.

The symptom in question, especially when limited to the purely subjective phenomenon pain, and unaccompanied by any discoverable local lesion, may appear a trivial matter; nevertheless, a chronic, long-lasting pain or tenderness of the foot is often so disabling, by interfering with locomotion, that the importance of correct diagnosis, prognosis, and treatment is by no means commensurate with the apparent insignificance of the ailment complained of. Moreover, although the causes of pain in the foot are very diverse, and their connection with this local manifestation is often remote and obscure, pododynia, considered only as a symptom, has not unfrequently a real diagnostic interest and value; and is, therefore, I think, worthy of attention, from a semeiological point of view. Without further apology, then, for dwelling upon so small a topic, I will first give a short account of my case, and then add such information as I have been able to collect on the subject of the disease from which my patient was suffering, as well as concerning the other forms of pain in the foot occasionally encountered in practice:—

CASE. A large, heavy man, about forty-five years of age, stout and somewhat plethoric in appearance, but in other respects looking robust and healthy, came to my office in August, 1877, complaining of a pain in the right heel. In answer to questions, he informed me that for some years before he had occasionally noticed urinary deposits, "brick-dust," together with slight attacks of temporary irritation of the bladder. He had also had "rheumatic" pains of uncertain character. No other morbid antecedents could be elicited. The pain was first felt about six weeks before his visit. He remembered having slipped and struck his heel, a few days previously, but this accident seemed a trivial one, and he attached, at the time, little or no importance to it.

At the time of his visit, strong pressure showed the existence of a tender spot on the sole of the right heel, about two inches from the posterior extremity of the *os calcis*. No other symptom was detected by a careful examination. The appearance of the part was perfectly normal, heat, redness, and swelling being entirely

absent. The patient was quite free from pain so long as he kept quiet, and he walked into my office without limping; but when he went even a moderate distance on foot, the pain soon became sufficiently acute to render further walking very uncomfortable, and caused a degree of lameness which hindered him very materially in the accomplishment of his bread-winning duties, the latter being those of a business-agent and errand runner, and keeping him a great deal on his feet. The diagnosis entered in my record of the case was "confusion: pain kept up by walking." I advised complete rest for a week, and the use of an alkaline mixture, in which twenty-five grains of citrate of potassium were to be taken thrice daily.

The patient returned two months later in the same condition as when first seen. The pain had ceased during abstinence from walking, recurring, however, as soon as he resumed his habitual occupations. Moreover, the other foot had become similarly affected, with a pain in the *tendo Achillis*. I then advised counter-irritation by means of tincture of iodine, together with the internal use of iodide of potassium, in doses of five grains, thrice daily. I failed to see the patient again, but have since been told by a mutual acquaintance that he had remained without improvement. I also learned that, before applying to me, he had been under the care of one of our most experienced surgeons.

REMARKS. Not long after the disappearance of this dissatisfied and unsatisfactory patient, I came across a description of his trouble in a book recently published by Dr. Gillette,¹ a surgeon of the Paris Hospitals. In this work, Dr. Desprès, of Paris, also a hospital-surgeon, is quoted as having bestowed the name of "policeman's disease" (*maladie des gardiens de la paix*, the latter designation being a euphemism which, after the downfall of the Empire, replaced the abhorred term *sergent-de-ville*) upon a painful affection of the foot, originating in a deep-seated contusion of the adipose cushion which covers the *os calcis*, and perpetuated by pressure undergone during locomotion. This ailment had, it seemed, been first described, many years ago, in 1833, by Velpeau.² It had also been, more recently, the subject of an essay by Dr. Fabre.³ According to Desprès, whose cases were chiefly observed among the Paris policemen, the pain generally affects first the right heel. It diminishes or subsides altogether during rest, but recurs, with or without implication of the other heel, when walking is resumed or persisted in.

Such is the "policeman's disease" of the French. I once inquired of Dr. Samuel A. Green, who, in his capacity of city physician, is often called upon to attend our sick or disabled policemen, whether among the latter he had ever met with such cases of painful heels. He had, however, had no such experience.

Pain in the heel, or sole, unattended by any objective symptoms, occurs under the following varied conditions:—

(1.) As an irradiated, reflected, or so-called "sympathetic" pain, in cases of *urethral stricture*, it has been observed by Luxmoor, Brodie, and many others.⁴

(2.) In cases of *osteal calculus*, "one of the most

interesting examples of this," says Von Pitha,¹ "occurred in the person of a colleague, Dr. Reisch, of Prague, who, in 1857, was freed from a large stone by lithotripsy. . . . He indicated, as one of the most precise symptoms of the calculus, a sensation as if he were standing with his left foot on a red-hot plate. With each successive diminution of the size of the stone, by means of the operation, the circumference of this burning plate seemed to diminish, and at last only a small edge of the sole remained the seat of this reflected pain. This remnant, however, continued obstinate after I had, as I believed, removed all the detritus, and when exploration failed to detect anything within the bladder. In spite of my denial, the patient insisted determinedly that, according to his sensations, some small fragments still existed at the left side of the fundus of the bladder. I examined him again, and at the end of a few weeks found, at the spot which he had indicated, a small fragment concealed in a fold of the mucous membrane. When this was removed, all pain in the sole disappeared, and the patient, for the first time, expressed himself relieved."

(3.) Similar irradiated or reflected pains in the foot are occasionally experienced in *cysto-prostatitis* or inflammation of the neck of the bladder. A patient of mine, somewhat advanced in years, had suffered for several years from obstructive hypertrophy of the prostate, with complete retention of urine, requiring the habitual daily use of the catheter, and complicated by chronic catarrh of the bladder. He had also had a phosphatic vesical calculus, which was removed by lithotripsy, partly by Professor Guyon in Paris, and partly by myself after the return of the patient to this country. He had for several months been afflicted with a most painful and harassing complication, namely, a chronic cysto-prostatitis, liable to frequent acute or subacute exacerbations. A considerable degree of relief, by the way, of the distressing and almost ceaseless vesical tenesmus caused by this inflammatory affection accrued from the use of intra-prostatic injections of strong solutions of nitrate of silver, — varying in strength from one in fifty to one in twenty parts of water, — practiced with Guyon's injector, at intervals varying from three or four to six or seven days. In this patient, curiously enough, every paroxysm of prostatic pain, whether caused by movements in bed, by locomotion, by calls to urinate, by catheterism or by the applications of nitrate of silver, was and still is liable to be accompanied by a sharp, distinctly localized pain in the ball of the left foot, the sensation then felt being compared by him to that which would be caused by treading with the bare foot upon tacks or broken glass. The pain at the neck of the bladder was of the same description, as if due to the presence of a sharp, jagged foreign body, so as to lead to repeated explorations for calculus under ether; this pain, also, is left sided, being referred to the left side of the vesical neck and rectum.

(4.) In *cystalgia* or neuralgia of the neck of the bladder, Von Pitha² himself, suffering from this neurosis, was actually sounded for stone as often as five times, by his own desire, so closely were the symptoms of vesical calculus simulated by his crystalgic paroxysms. A very severe neuralgia at the same time also

affected the heel, the pain, at its moments of greatest severity, taking on exactly the sensation that would have been experienced if the periosteum were being forcibly separated from the *os calcis*. "The pains are so intense," says Von Pitha, "and the deception so complete, that I am under the conviction that if the subperiosteal excision of the *os calcis* were being executed, the pains would only resemble in nature and severity those which I suffer during the acute paroxysm."

(5.) In *gout*, besides the pain attending the acute inflammatory attacks of dermatitis, lymphangitis, and cellulitis, caused by the deposits of biurate of sodium, sharp pains in the feet, particularly in the heel, at times occur without any objective symptoms. Sir James Paget³ cites pain in the heel as one of the many lesser signs of gout. "Of course," he says, "it was not meant that no further inquiries should be made, but only that pain at the heel ought to suggest gout, and lead to further questions on the point. Similarly, pain in the tendo Achillis, especially in elderly persons, who had sustained no injury, was due, with very few exceptions, to some degree of gout." Elsewhere⁴ he says, "I cannot remember to have heard any patient complaining of spontaneous pain in his tendo Achillis, except such as I knew to be by inheritance disposed to gout or a lithic acid diathesis. Pain in the heel of an elderly person has, generally, the same meaning. . . . 'Burning soles' and the less frequent 'burning palms' generally signify a gouty constitution or one closely allied to it, and so do the sensations of hot, tingling, and burning patches of the skin of the thighs, without external appearance of redness or eruption." Dr. Dyce Duckworth,⁵ of Saint Bartholomew's Hospital, to whose extensive and painstaking observations we owe much valuable information touching the protean signs of the gouty constitution, testifies to the same effect as follows: "Deep-seated pain in the heel has been recognized as of gouty origin. The sensation is compared to the feeling of a foreign body being implanted there, such as a bullet. And it is noteworthy that this is sometimes a symptom of a renal calculus which may itself be the outcome of a gouty taint. The pain is sometimes distinctly in the tendo Achillis." Charcot⁶ mentions the tendo Achillis as one of the ligamentous structures in which uric acid is liable to be deposited in overtly gouty subjects. A discussion took place a few years ago in one of the medical societies of Paris on *pain in the heel, or talalgia, and its treatment*, in which several speakers took part. It was agreed that the pain was often due to a gouty or rheumatic diathesis, and the use of salicyate of soda, in daily doses of one or two drachms, was said by Buequoy, Panas, and Desprès,⁷ to be often efficacious.

The burning soles and palms, alluded to by Sir James Paget, may, perhaps, be considered more or less analogous to the distressing and at times painful affection of the extremities, recently described by Dr. S. W. Mitchell,⁸ under the title of A Rare Vaso-

Motor Neurosis. In this chronic and most refractory disease, however, for which the descriptive name of *erythromelalgia* is proposed by Dr. Mitchell, the subjective sensation of heat or scalding is accompanied by a marked temporary flushing or hyperæmia of the affected parts, with redness and warmth of the surface. This affection, therefore, cannot properly be included in the category of purely subjective ailments considered in this paper.

A patient of my own, an elderly lady, coming from a distinctly gouty stock, who had suffered severely somewhat over a year ago from gall-stones, with severe hepatic colic and jaundice, and who has lately placed herself, by my advice, under the care of Dr. J. C. White, on account of a persistent and most distressing generalized pruritus, has also suffered, since last October, from what I take to be *erythromelalgia*, namely, paroxysms of painful burning of the feet, accompanied, according to her report, by flushing of the skin, and occurring mostly at night in bed.

(6.) *Renal calculus* occasionally gives rise to a pain irradiated to the heel, as stated by Dr. Dyce Duckworth in the passage quoted above.

(7.) In *gonorrhœa* pain in the heel is described by Fournier,¹ Panas, and others, as an occasional manifestation, more or less akin to the various forms and localizations of so-called "gonorrhœal rheumatism," which affects the articular and tendinous synovial membranes and the bursa. It was first described as affecting the heel in this disease by Swediaur.

(8.) In *syphilis*, also, according to Fournier,² the same phenomenon is met with. Here, as in gonorrhœa, the pain is attributed by him to a bursitis.

(9.) In *locomotor ataxia* the heel may be the first or, for a while, the principal seat of the lancinating or boring pains, characteristic of the first stages of that strange disease. A patient whom I had occasion to see a few years ago, and whom I sounded for stone, at the request of his medical attendant, was suffering from occasional painful paroxysms of vesical and rectal tenesmus. For several years previously he had experienced sharp, boring pains (the *douleurs térébrantes* of Charcot) which had first attacked the heel. He subsequently developed ataxic symptoms, with staggering gait. Dr. Seguin, describing the symptoms of locomotor ataxia, says that "patients usually give up in despair the attempt to show you every spot in which they have suffered, and they generally indicate as foci of pain the heel, instep, and thigh." Dr. Buzzard also expressly mentions the heel as frequently the seat of pain in tabes.

(10.) Lastly, an obscure form of pain in the feet has been very briefly described by Prof. S. D. Gross,³ under the name of *pododynin*. It shows itself in the form of great tenderness to pressure, and is met with in certain sedentary classes of artisans, particularly in tailors.

Such, mainly, are the manifold conditions under which the purely subjective symptom, *pain in the foot*, may occur. This little ailment is not unfrequently as puzzling and refractory to the medical attendant as it is annoying and disabling to the patient. This consideration will, I trust, be accepted in justification of the attention which I have ventured to bestow upon the subject.

INDEXES¹ TO MEDICAL LITERATURE.

BY FRANCIS H. BROWN, A. M., M. D., BOSTON.

"I FOR my part venerate the inventor of indexes, and I know not to whom to yield the preference, either to Hippocrates, who was the first great anatomizer of the human body, or to that unknown laborer in literature, who first laid open the nerves and arteries of a book."—DISRAELI.

THE simple word index is to most readers of books an unimportant one, suggesting a certain amount of machine work by a printer's assistant or an inexperienced hack, who has hastily galloped over the author's pages, culling here and there a title, and putting it down, often with the most egregious misapprehension of the writer's idea. But to a real worker with books the index is *the book*, and he can often better forego the book than the index. I use the word index in the sense which we now give to it. Index, Table, Register, Calendar, Summary, Syllabus, have all been used in the past of literature with much the same significance; but as we now reserve the title Contents for the continuous summary of the book, we give the title Index to the alphabetically arranged analysis of the contents.

Dr. Allibone in his Dictionary of Authors thus quotes from a writer in the *London Monthly Review*: "The compilation of an index is one of those useful labors for which the public, commonly better pleased with entertainment than real service, are rarely so forward to express their gratitude as we think they ought to be. It has been considered as a task fit only for the plodding and the dull, but with more truth it may be said that this is the judgment of the idle and the shallow. The value of anything, it has been observed, is best known by the want of it. Agreeably to this idea, we, who have often experienced great inconveniences from the want of indices, entertain the highest sense of their worth and importance. We know that in the construction of a good index there is far more scope for the exercise of judgment and abilities than is commonly supposed. We feel the merits of the compiler of such an index, and we are ever ready to testify our thankfulness for his exertions."

Authors and editors are often deterred from making an index by the fear of labor, but this is no excuse; if the book is worth publishing it is worth an index. Lord Campbell proposed that an author who published a book without an index should be deprived of the copyright act, and our own countryman, Horace Binney, has expressed the same idea. Baynes, the author of the archaeological epistle to Dean Milles, puts it with much more force and fully as much point, at least he is thus reported by the learned Francis Douce: "Sir, my friend John Baynes used to say that the man who published a book without an index ought to be damned ten miles beyond hell, where the devil could not get for stinging nettles." How often do we feel disposed to coincide with such as these in searching

¹ The use of the plural form *indexes* in place of *indices* may excite comment. As will be seen in the quotation employed, it has the sanction of Disraeli; it is also authorized by Mr. Cutler, the learned librarian of the Boston Athenæum, and is given as the preferable form by both Worcester and Webster, while Mr. Whentley, — from whose admirable book on *Indexes* I have taken many ideas, — referring to a quotation from *Troilus and Cressida*, says, in a footnote, "I would here, under cover of our great poet's name, protest against the use of the plural *indices*. As long as a word continues to take the plural form of the language from which it is borrowed, we cannot look upon it as thoroughly naturalized. Surely index may be considered an English word when it was treated as such by Shakespeare."

up some subject in the works of modern English and French authors, as innocent of indexes as a stone of meat. Carlyle very justly says, "Books born mostly of chaos, which want all things, even an index, are a painful object." Truly may it be said it is the *soul* of a book.

In that industriously and pleasantly written book of Mr. Wheatley, of Manchester, What is an Index? — which will well repay any one's reading, — the author says, "An ideal indexer needs many high qualifications, but, unlike the poet, he is not born, but made. He must be a good analyzer, and know how to reduce the author's many words into a terse form. He must also be continually thinking of the wants of the consultant of his index, so as to place his references under the heading that the reader is most likely to seek."

There is so much work to be done, and more than ever and elsewhere in this bustling, seething age and country, that it is not well to go over and over the old road which others have trod. Hardly an instrument is made or a method of treatment suggested but its counterpart is found in the old-time days of Paré and Celsus, hidden away under the dust of ages. If this work can be saved by more or less full indexes of the past we cannot fail of making more speed in the future.

In medicine we have fallen behind the rest of literature in comprehensive indexes. Serials have been published for years, rich in the investigations, the experiments, the thoughts of the best of the profession, but the periodicals are closed volumes, except to those who are willing to wade through often imperfect indexes at the close of the volumes. Who can lay his hand in a moment on Dr. Ware's Treatment of Delirium Tremens, or Dr. Mason Warren's Hermaphroditism, or Dr. Bowditch's Anomalous Development of Tubercle in our own Medical Journal, classical articles each of them, and how few can devote the time to hunting them up in our busy everyday life.

It should be a cause of gratification and pride that our own country and age is soon to do so much to wipe out this opprobrium to our profession. Fore-shadowed by the specimen fasciculus of a catalogue of the National Medical Library, and with the first volume before us, we cannot fail to look with the greatest interest for the succeeding volumes of this catalogue of medical literature. With this aid the pursuit of investigation in our profession will be comparatively easy, and we can heartily join the talented author in his prayer to Congress for the means to bring it before the medical public. "What is the value of such an index to the people of the United States, as compared with an expedition to the north pole, five miles of subsidized railway, one company of cavalry, or a small public official building?" Under the same skillful hand the Index Medicus has passed through its second year, a publication which is perfectly indispensable to true workers, and it should have a list of subscribers which, at any price in reason, ought to secure its publishers and its editors from the slightest chance of loss. A solemn sense of duty should impel each one to send his subscription to the publisher, and help him to bridge over this critical period of its existence.

The bibliographical lists which have appeared from time to time in our serials on special subjects, and the reports on special subjects of medical literature are invaluable, and are worth many times the space they take. The bibliography of albuminuria by Dr. Ellis in the Medical Journal, of cremation by Dr. Adams in

the State Board of Health Report, of Dr. Jeffries in his work on color-blindness, and of various writers on their special topics in Buck's Treatise on Hygiene and Public Health, and those of the New Sydenham Society make the road an easy one to plodders in the same direction.

The Pathological Society of London, the Royal Medical and Chirurgical Society, the Royal Society of London, and the College of Surgeons of London have excellent classified indexes of their libraries; the *British and Foreign Medico-Chirurgical Review*, the *Dublin Medical Journal*, the *Edinburgh Medical and Surgical Journal*, the *London Medical and Physical Journal*, the *Medico-Chirurgical Review*, and the *New York Medical Journal* give valuable indexes of their material. The work of Plocquet and Reuss fairly covers medical literature previous to 1800. And in this year Reuss commenced his *Repertorium Commentationum a Societatis Literariis Editorum*, which was continued for twenty years and completed in sixteen quarto volumes. Before this Albert von Haller had issued his *Bibliotheca Botanica* (1771), *Bibliotheca Anatomica* (1774-77), *Bibliotheca Chirurgicalia* (1774-75), and *Bibliotheca Medicinæ Practicæ* (1776-78).

We cannot fail to mention a most valuable work, published by the New Sydenham Society in 1877, *The Medical Digest*, by Dr. Richard Neale. The preparation of bibliographical indexes was one of the original objects proposed by the New Sydenham Society, and this epitome, on all the topics of medicine, made up from fifteen of the best English and American serials of the day, gives a key to the best work that has been done for the past forty years. It is the outcome of more than thirty years' continuous labor. "Week after week," says Dr. Neale, "cases full of interest, observations of the greatest value, modes of treatment applicable to a variety of circumstances, are found in the pages of such publications. These are read and appreciated at the moment, but the memory fails to recall them when needed, and much valuable time is often lost in searching back numbers and wrong volumes for what, after all, will, most probably, be missed."

A general index of the Reports of the Massachusetts State Board of Health, including the entire series from the creation of the board, has recently been made by the writer of this paper. It opens up a vast amount of valuable material on general hygiene and on special topics of the utmost importance to the good of the community.

All these leave a vast amount of professional literature still lost in the forgetfulness of the past. In view of such an accumulation of material hidden in hundreds of valuable periodicals and other works, we cannot fail to be impatient for the appearance of Dr. Billings's promised volumes, or desirous for the formation, on this side the water, of an organization to supplement the work so well started by the Index Society of London.

For a few volumes back the index of the Boston Medical and Surgical Journal has been arranged on a definite plan, by authors and subjects; the subject catalogue following, as nearly as may be, the nomenclature — not a perfect one, but, perhaps, as good as we can command at present — of the Royal College of Physicians of London. Every disease relating to the nervous system is entered under its appropriate head, and every specialist in nervous disorders can see at a glance what has been written on his own subject. The same plan

is carried out in the various branches which have always been recognized in general practice, or which are now cultivated by persons particularly devoted to them, under the headings diseases of the circulatory, respiratory, digestive, and other systems; while bibliography, hygiene, health and boards of health, hospitals, education, poisons, Vienna, are some of the topics which will indicate the mode of classification; under these or some other similar easily-distinguished head every article is placed, as well as under the name of the author. It can hardly be possible that one should fail to find an article with the greatest ease; it cannot fail to strike one that this putting together under distinct heads must facilitate study and investigation; and the reader who dimly recalls an article in midwifery, by Dr. Blank, in a volume some years back, is not forced to search it laboriously up under the titles, obstetrics, labor, pregnancy, gestation, placenta, uterus, cord, and half a dozen other topics, through a series of volumes.

Criticisms of such an index as has been adopted by the *Boston Journal* may be and have been made; it is better to meet such fairly and to place every reader in reach of the author and in accord with the editor. The name or the title of an article may be omitted; an accident of this character may happen in any one's experience. A word or note of apology to the aggrieved party ought to be amply sufficient to heal any such wound. Unfortunately an index which should be the most accurate of all things is especially liable to accident. Any omission or slip of the author's pen leaves nothing by which it can be detected until its discovery, perhaps years after, calls forth a groan from some disappointed searcher. A single letter or figure imperfectly formed and wrongly read by the printer makes the reference valueless. The context gives no aid to the proof-reader in a matter in which printer's errors are most liable to occur. It is impossible to devise any check system or balance sheet by which inaccuracies can be detected. Again, modern pathology has changed the classification of diseases, so that some have a different place now from that recognized by the older members of the profession; pulmonary phthisis may be a disease of the lungs to one, while to another it may be a general disease and to be classified with scrofula,—as is done in the nomenclature of the College of Physicians. Herpes zoster may be a cutaneous disease to one, but a neurosis to another. Sanguineous apoplexy and pulmonary extravasation may be looked for under the nervous and respiratory systems respectively, or, by another person, under the circulatory. The true method of indexing all cases which admit of doubt is to place them under both heads, and it is the custom of the indexer of the *Journal* to follow this rule. Indeed, some titles require half a dozen entries, in order to meet the possible needs of many readers.

Not the least important part of medical literature is contained in pamphlets and monographs, naturally ephemeral in their character, and easily lost by those who do not make collections of such material. A text-book covers the whole ground of a specialty, with brief and often entirely unsatisfactory references to individual topics, but a monograph is the elaborated work of one who has given especial thought to the subject under investigation. The best, the freshest, the most thorough work in medicine is contained in pamphlets, which, in the hands of most private individuals, are soon lost and quickly pass out of mind. The labor of cataloguing, classifying, and binding is too great for most persons,

and without such catalogue the collection is comparatively valueless. Few of our libraries ever make any systematic attempt to collect pamphlets, and those which reach them by chance are bundled together without any thought of indexing. The Boston Medical Library has now a collection of 8000 medical pamphlets carefully catalogued, the Boston Public Library as many more, and the National Medical Library surpasses these with its 40,000 precious pamphlets.

The librarian of the Mercantile Library of San Francisco, in speaking of general literature, gives a key-note which is as valuable in medicine as in a wider field. "A thorough collection of the periodical literature of the day constitutes a part of every library of note, acknowledged to be the most important and useful. Its value in a public library cannot be over-estimated. It offers the student an epitome of all history, science, and art in the past, and a continuance of the same in every department even to the present day. It contains the latest improvement in science, the freshest turn of thought. With a completion of Poole's Index to Periodical Literature to date, the searcher after knowledge would have, in a complete magazine collection, a store of information inexhaustible and, in worth, beyond computation."

RECENT PROGRESS IN THE THEORY AND PRACTICE OF MEDICINE.¹

BY GEORGE B. SHATTUCK, M. D.

CHICKEN CHOLERA. A STUDY OF THE VIRUS.

M. Pasteur has at last communicated the long-awaited results of his study of this malady, with the conclusions he has reached by successive cultivations and inoculations of the micro-organism which constitutes the infecting virus. The paper² is valuable, and readily suggests a wider application of the facts and principles established by the writer's experiments.

He lays down, to begin with, the following propositions, based upon previously published observations: (1.) Chicken cholera is an extremely virulent disease. (2.) The virus is a microscopical parasite, easily propagated by culture outside the bodies of its victims; and hence the possibility of obtaining this virus in a perfectly pure state, and of an indisputable demonstration that it is the sole cause of the disease and of resulting death. (3.) The virus offers various degrees of virulence. (4.) These degrees are not merely established by observation of natural conditions, but may be produced by the experimenter at will. (5.) As is in general the case with all contagious diseases, chicken cholera does not recur, or rather recurrence is of such a mild type that protection can always be brought to such a point that inoculation of even the most active virus will finally produce no result. (6.) From the preceding propositions it is evident that in chicken cholera there are forms of the virus which bear the same relation to the most active virus that human vaccine matter does to the virus of small-pox. Just as the vaccine virus, from a mild malady — vaccinia — affords protection against the severe disease, — variola, — so the virus of chicken cholera presents phases of diminished intensity, causing the disease, but not death, and under such conditions that after recovery the animal is proof

¹ Concluded from page 636.

² Bulletin de l'Académie de Médecine, Séance du 26 Octobre, 1880.

against inoculation by the most active form of the poison. There is this difference, however, in favor of the investigations upon chicken cholera: whilst the exact relations of vaccine matter and variola are still in dispute, we are certain that the diluted virus of cholera is derived directly from the very active virus of that disease; in other words, that the fundamental nature of each is the same. This fact that there are various degrees of activity in a poison whose active principle is a micro-organism, which can be isolated as one isolates the ferment of beer or the mycoderm of vinegar, is sufficiently remarkable. It is, however, entirely consonant with the variable virulence in different epidemics of all these virulent diseases; of small-pox itself, for example.

M. Pasteur next proceeds to show that these variations in intensity of the virus and of the disease are at the control of the observer. He took the most active virus procurable, the inoculation of which was certain death, and found by prolonged experiments (here being the cause of delay in the communication of his present observations) that the virulence of the poison was not modified by propagation through successive generations, but only in proportion to the time elapsing between removal of the parasite from its first to its final abode, and this modification is, moreover, shown by experiments to be in direct proportion to the exposure of the virus to the influence of atmospheric air, to the action of oxygen.

The gradual modification of the virus is noticed at first by a longer interval between inoculation and death; when carried farther, by recovery after severe symptoms; and, finally, by recovery after mild symptoms. M. Pasteur has been unable to discover any difference in the microscopical appearances of the parasite, whether of an active or of a mild virus.

This modification of the chicken-cholera virus by exposure to the influences of oxygen, M. Pasteur remarks, is more than an isolated fact; it puts us in possession of a principle, and we have in it the whole history of the limitations of great epidemics.

Mr. Toussaint¹ during this same period has been experimenting at Allort and at Lyons as to the possibility of securing immunity against *charbon* by inoculation with a diluted culture-liquid of the characteristic micro-organism of that disease. His results have been sufficiently successful to cause the further prosecution of these investigations to be awaited with impatience. His method was to defibrinate the blood of an animal attacked with *charbon* by filtration or by heating to 55° C., in order to eliminate the bacteria; this blood was then injected under the skin of another animal, which in the course of twelve to fourteen days was found to be completely protected against *charbon*. If the parasite is to be regarded as the active element of the poison in these virulent diseases, there are evident contradictions between M. Pasteur's methods and results and those of M. Toussaint, which should be reconciled. The results so far observed, however, may be accepted as facts, and are encouraging as indicating the possibility of progress in securing methods of artificial protection against contagious diseases in general.

THE EPIDEMIC AMONG THE WORKMEN IN THE ST. GOTHARD TUNNEL.

Dr. E. Bugnion,² of Geneva, describes the cause of the singular epidemic prevalent last spring, and which

still prevails, among the workmen of St. Gothard. One reason that the cause of this epidemic, which is a little worm known as *ankylostomum duodenale*, was not immediately recognized, was the refusal of the authorities to allow post-mortem examinations. In one hundred and seventeen deaths which took place prior to the publication of the government report in June, 1880, only a single examination was made. Dr. Bugnion says:—

This parasite had been hitherto entirely unknown in Switzerland; it is not unknown in Italy, but is more common in hot countries, such as India, the Antilles, and Brazil, and especially in Egypt, where it causes the disease denominated the Egyptian chlorosis. This latter fact was brought to light in the year 1854 by Griesinger, a distinguished German physician, who passed many years in Egypt; and to whom we owe, as well as to his countryman Bilharz, important researches as to the parasitical diseases of that country.

The *ankylostomum* is a nematoid worm, and consequently belongs to the same order as the trichina, the oxyuris, the ascaris lumbricoides or children's worm; but that which renders it much more prejudicial than the latter is the fact that, instead of feeding on the contents of the bowels, it attaches itself like a little leech to the mucous membrane of the duodenum, of which it sucks the blood. Its mouth is armed for this purpose with a cup-like sucker, on the edge of which are fixed three pairs of hooks, with which it fastens itself to its victim. At the entrance of the œsophagus are found, besides, three movable blades, which work like little lancets, and probably serve to make incisions in the portion of the mucous membrane seized by the sucking organ.

Large ecchymoses owing to the bite of the *ankylostomum* are often found in the mucous or submucous lining of the intestines; and the repeated intestinal hæmorrhages produced by its attacks may be considered as the principal cause of the aggravated anæmia and increasing weakness which are generally observed in such patients.

The largest of these worms are always females; they measure about half an inch in length (12.618 millimeters); the male is about half the size. The smallness of these parasites is compensated for by their number, for they are often found by hundreds in the intestines of the individuals who have died of this disease. Dr. Tarona, at Varese, counted as many as 1250 specimens of *ankylostomum* in the evacuations of a single patient, after the administration of ethereal extract of male fern.

The external symptoms of the complaint are an increasing paleness of the skin, lips, etc., and it is accompanied in serious cases by swelling of the feet and a puffiness of the face, caused by the excessive fluidity of the blood. The pulse is quick and feeble; the patient suffers from palpitation and giddiness; he feels a great lassitude, and soon becomes unable to work. With these symptoms, which are those of an aggravated anæmia, are generally connected a derangement of the digestion and cutting pains in the abdomen. This condition may last for years, and is too often terminated by death. The patient finally sinks under dropsy and exhaustion.

The *ankylostomum* is extremely prolific; each female produces thousands of eggs. Happily for the patient, the development of these does not take place in the bowels, otherwise he would certainly lose his

¹ Garnier's Dictionnaire annuel, page 139, 1881.

² British Medical Journal, i. p. 382, 1881.

life. The eggs must be evacuated; the embryo continues its evolutions externally, and is hatched in water. It is in drinking this water containing the germs of ankylostomum that the man introduces this dangerous visitor into his body. It is easy to understand that, owing to the want of cleanliness on the part of the St. Gothard workmen, the epidemic has extended so rapidly.

The first of these cases was recognized by Professor Pozzolo last spring. It was that of a workman who had been employed in the great tunnel, and died soon afterwards in the hospital at Turin, with symptoms of aggravated anaemia. The post-mortem examination revealed the presence of numerous specimens of ankylostomum in the small intestine. Three other cases, observed in the same town by Drs. Concato and Perroncito, were the subject of a communication to the Académie des Sciences in Paris, in the sitting of March 15, 1880.¹ The parasite was also identified, but in no great numbers, on March 10, 1880, at Airolo, at a post-mortem examination, by Dr. Giaccone, one of the physicians of the St. Gothard Company.

Notwithstanding these important discoveries, hesitation was at first felt in attributing to the presence of this noxious worm the cases of anaemia which were constantly increasing among the workmen. In consequence of the ankylostomum having been rarely observed up to this time in that part of Europe, it seemed more natural to refer the complaint to vitiated air, want of light, unsuitable food, — in short, to the defective sanitary conditions in which the workmen lived.

The evidence, however, became irresistible after Dr. Sonderegger² had treated a young engineer of the works. The patient showed all the symptoms of Egyptian chlorosis, and after having taken santonin (two decigrams) with calomel (five decigrams) evacuated the ankylostomum in large numbers.

Similar cases were not long in appearing. Thus, in the month of November, Professor Bäumler³ discovered the parasite in the case of a Tyrolean workman, who had left the Gothard, and who had been admitted into the hospital of Freiburg in Breisgau.

In December six instances of the same thing were observed by Dr. Schönbachler, in the Schwyz Hospital, among the workman who had been employed in the tunnel. One of them soon sank, and about three hundred specimens of ankylostomum were found attached to the mucous lining of the duodenum and jejunum.

During that time twelve new cases were reported at Turin by Dr. Perroncito and others, but none of them had a fatal result, in consequence of the successful administration of fifteen to thirty grains of ethered extract of male fern with two and a half to three and a half drachms of tincture of male fern during two or three days successively.

Finally, we can add a last case, that of an Italian workman, who had been at Goschenen up to October last, and who, after having worked for some months in another part of Switzerland, was obliged, in consequence of increasing anaemia and weakness, to seek medical aid in the Infirmary of Rolle during the month of January. Dr. Dumur, the director of this institution, has had the kindness to send eight specimens of ankylostomum (three males and five females) evacuated by this patient. The presence of the parasite was first

placed beyond doubt by microscopic examination of the eggs which had been expelled. These little bodies, which measure hardly more than one six-hundredth of an inch (one twentieth of a millimeter), nevertheless offer to the physician an important aid to diagnosis, by their being easily distinguished from those of the other hæmatoid worms infesting the human body.

The eggs of the *Oxyuris vermicularis*, which might otherwise be confounded with those of the ankylostomum, as being about the same size, are distinguished by the greater elongation of the shell, which is more convex on one side than on the other, and is furnished with an operculum. The embryo ready formed may be perceived within, while the eggs of the ankylostomum are generally expelled at an earlier stage of development.

RELAPSE OF TYPHOID FEVER, ESPECIALLY WITH REFERENCE TO THE TEMPERATURE.⁴

DR. IRVINE published some articles on this subject in the *Medical Times and Gazette* during the year 1879. These form the basis for a crown octavo volume of 143 pages which has lately appeared. During his service at Charing Cross Hospital the writer became strongly of the opinion that relapse in typhoid fever is much more common than is generally supposed; that while primary relapse is common, second relapses are not uncommon, and third and fourth relapses may be met with. He thinks it difficult to overestimate the value of temperature as a clinical guide during apparent convalescence from typhoid fever. The thermometer will be often found the only efficient agent to clear away obscurities. The observations should be continuous and frequent, and the typical curvatures of the daily chart are of more value than the height of the temperature. Relapses are over and over again set down as primary attacks. The records of thirty-one patients are reported which furnish forty-six cases of relapse, each case being accompanied by a careful chart more instructive than the text. The reports offer instances of, (1.) Single relapse of simple nature; (2.) Relapses either irregular or complicated; (3.) Double, triple, and quadruple relapses; (4.) Recrudescences, intercurrent relapses, and cases likely to be confounded with relapse; (5.) Total relapses, simple or complicated. In twenty-nine of the relapses recorded, out of a total of forty-six, the apyrexial interval between the primary attack of typhoid and the relapse could be determined with complete accuracy. These twenty-nine relapses were divided amongst twenty-three patients, three of whom had each three relapses. The average duration of the interval was a fraction over five days; in three instances the duration was ten days, and in four there was no appreciable interval. The average interval of five days is scarcely half that met with by Dr. Murchison. The absence of an apyrexial interval extending over at least twenty-four hours in four of the cases contradicts the assertion of some writers of eminence that typhoid-relapse never occurs without a clear apyrexial interval between it and the primary disease. In almost all the cases of uncomplicated typhoid the temperature was during the "intervals" normal morning, noon, and night, and oftentimes subnormal—below 98° F. As a rule the interval preceding a relapse is marked by subnormal temperatures. Speaking generally, Dr. Irvine is disposed to say that if one relapse occurs, a second should be looked for and guarded against.

¹ See Comptes Rendus, page 619.

² Correspond. f. Schweiz. Aertze, 1880, 29.

³ Correspond. f. Schweiz. Aertze, 1881.

⁴ By J. Pearson Irvine, M. D., B. Sc. F. R. C. P., London. With Temperature Charts. London: J. & A. Churchill. 1880.

Of the thirty-one patients in his series at least five had a third relapse, while in one case a fourth relapse occurred. The duration of relapses is uncertain; taking twenty-nine instances of relapse out of this series — instances observed from first to last, where complications could be positively excluded, and where treatment was never directed to cutting the disease short — the average duration of relapse was about twenty to twenty-one days.

Dr. Murchison found the average duration of relapse about fifteen days. It is almost certain that, where two or more relapses occur in a patient the later relapses are, if no accident happens, shorter than the preceding ones; just as the first relapse is, as a rule, shorter than the primary typhoid.

How does relapse as judged by the thermometer, in particular, declare itself? In most cases the recurrence of the disease is characterized by an unexpected and continuous elevation of temperature. The fever begins suddenly, and though remissions may occur daily, it increases until it reaches its height on the fifth evening of relapse. The remissions are of little diagnostic importance. But where complications are absent from first to last, the highest temperature is met with on the fifth day. From this day the temperature maintains nearly the same level (with morning remissions varying in degree) until the eighth or ninth day, when it falls decidedly and, beyond all doubt, critically. Dr. Irvine considers it diagnostically and prognostically, most important to observe the temperature in relapse from hour to hour during its eighth and ninth days. The fall in temperature at this period he regards as a most favorable omen, and the fatal cases among those recorded by him are marked by its absence. On these critical days the temperature may be found from three to six degrees or more below its previous level. These observations are supported by the charts accompanying the cases. This critical fall marks a stage of the disease and not its termination; a rise in temperature always follows. A third stage of the disease begins from the ninth day with a new accession of fever. On the tenth day, for example, the temperature may almost run up to previous levels; but afterwards there are gradual daily remissions of fever — great or small, but constant — until the disease is at an end, about the twenty-first day of relapse. The assertion that three stages are met with means simply that critical periods should be looked for. Such periods being the fifth, eighth or ninth, the fifteenth and twenty-first days of the disease, on which days it is particularly important to note the temperatures. Dr. Irvine entertains the view that relapse is due to the primary contagion, and that the reported cases of recurrence of a typhoid attack weeks, or even months, after a patient's convalescence, are in all probability merely cases of multiple relapse, for, unless the thermometer is used with daily regularity intermediate relapses may be very readily passed by.

DIPHTHERIA TREATED BY PILOCARPIN.

Dr. George Guttman, of Croustadt, reports a very favorable experience with pilocarpin as a remedy for diphtheria.¹ He first began to use pilocarpin for this purpose in April, 1879, and his experience at the time of writing extended over about a year and a half, and included a large number of cases both severe and mild. Its action was also tested by some of his colleagues

with equal success. The resulting secretion from the mucous membrane of the throat and fauces removes the false membrane without exciting an injurious inflammation, nor was any marked depression produced by the exhibition of the drug in the majority of Dr. Guttman's cases; where any such tendency was manifested stimulants in some form were administered alternately with the pilocarpin. He found it more advantageous to give the medicine by the mouth, and used the following formulas: For children, 17 pilocarpin muriat., gr. $\frac{1}{2}$ (0.02-0.1), pepsin, gr. 1-1 $\frac{1}{4}$ (0.06-0.08), acid hydrochlor., gtt. 2, aq. destill. 5jss (80.0). M. Sig. A teaspoonful hourly. For adults, 17 pilocarpin muriat., gr. ss-1 (0.03-0.05), pepsin, gr. 30 (2.0), acid hydrochlor., gtt. 3, aq. destill. 5s (240.0). M. Sig. A tablespoonful hourly.

So many writers have been tempted to believe that they had at last found a specific against this terrible malady, that a tenacious skepticism is sure to await the announcement of any new remedy, however promising. The action of the pilocarpin is, of course, a local one, and its effects, when operative, the gentle removal of false membranes from the mouth, fauces, and larynx. The secondary systemic poisoning by the products of local inflammation may also, perhaps, be thus avoided. It would certainly seem that the local action of the pilocarpin might in some cases be of much service. The general depressing effect of the drug should always be carefully guarded against. Dr. F. W. Vogel reports several cases thus treated in the *JOURNAL* for March 10, 1881.

ACCIDENTAL AND SUDDEN DISLOCATION OF THE LIVER, WITH RECOVERY.

Dr. A. Y. P. Garnett² reports what he considers to have been, and what the conditions as reported seem to justify him in regarding as a case of sudden dislocation of the liver. Such an accident must be, to say the least, excessively rare, and Dr. Garnett, after careful search, believes his case to be unique in medical literature. A woman, aged fifty, who had always enjoyed good health, and, though very stout, had led an active life, whilst stooping hurriedly to pick up some object from the floor, felt a sudden wrench or giving way on the right side. She felt, as she expressed it, that her "ribs had slipped in and the bowels had been thrown up, and bulged out." There was severe pain across the abdomen and chest, difficult respiration, a sense of suffocation, and consciousness of fullness and distention of the abdomen on the right side. She tried to walk, but found this occasioned so much nausea, pain, and faintness that she remained in bed. Dr. Garnett being summoned the next day, was led, as the result of a careful physical examination, to the conclusion that there had been a sudden and violent displacement of the liver downwards.

The patient remained in bed, on her back, with the lower limbs flexed on the pelvis, and woolen cloths, saturated with a warm solution of muriate of ammonia, constantly applied to the seat of pain. The following day the patient was found comfortable and free from pain or fever. Measurements showed a diminution in bulk of the abdomen. The diminution in bulk and alteration in the area of flatness upon percussion were still more marked the next day. A week's confinement in bed, followed by the application of a broad

¹ Berlin. klin. Woch., No. 40, October, 1880, s. 569.

² American Journal Medical Sciences, January, 1881, page 110.

elastic band around the abdomen, completed the treatment and the recovery. Dr. Garnett expresses a natural surprise that, considering the anatomical attachments and surroundings of the liver, the resulting mischief did not prove more disastrous.

A CASE OF WANDERING LIVER.

In connection with the preceding the following case¹ is worthy of notice:—

The following case is reported by Dr. Hochhalt:² A woman, fifty-five years old, who had in her youth been subject to jaundice, lifted a heavy sac about one year before she came under observation. At the time of that unusual exertion she suddenly experienced a sharp pain in the right hypochondriac region, and fell to the ground in an unconscious condition. Since then she constantly suffered from a feeling of weight and her right side was occupied by a movable, hard tumor. Her condition has remained unchanged, and, beyond attacks of temporary indigestion and obstinate constipation, she has no morbid symptoms.

The diagnosis of movable or floating liver appeared a proper one when the results of the physical examination were taken into consideration. These may be summarized as follows: first, the liver was not found in its normal position; second, in the hypogastric region a tumor, corresponding in its shape and dimensions to the liver, was discoverable; third, this tumor was movable; fourth, it could be returned, by manipulation and a suitable decubitus of the patient, to the right hypochondrium; fifth, the abdominal parietes were abnormally lax and flabby. As regards treatment, the patient was merely directed to wear an appropriate abdominal supporter.³

A CASE OF MOVABLE LIVER.

The *Lancet*⁴ reproduces an observation accidentally made on a physician by Dr. Chvostek, and recorded in the *Wiener Medical Blatt*. There were no symptoms whatever of anything wrong in the abdomen, and there was no history of violence or of any occurrence that threw light upon the condition. When the man stood up the upper and posterior border of the liver was felt to come forward from under the margin of the thorax, and to be six centimeters and a half below the tip of the xiphoid cartilage in the right parasternal line, and one centimeter below that point in the left parasternal line. The left end of the liver was plainly felt through the abdominal wall, and from it the anterior, or rather the lower edge of the liver could be traced arching down to the right, being in the middle line fifteen centimeters below the xiphoid process, and in the right nipple and axillary lines respectively seven and one-and-a-half to two centimeters below the edge of the thorax. The liver did not markedly descend on taking a deep inspiration. In the horizontal posture it could be replaced under the ribs to a considerable extent. In lying on one side the organ fell to some extent towards the dependent side. The lower edge of the suspensory ligament could be felt tightly stretched, but this produced no pain, and so completely absent were all symptoms that the condition was only discovered accidentally.

Hospital Practice and Clinical Memoranda.

DEATH FROM CARBOLIC-ACID POISONING FOLLOWING HYPERDISTENTION OF AN ABSCESS WITH A CARBOLIC SOLUTION.⁵

BY E. H. BRADFORD, M. D.

The following case is of importance as a surgical warning. Death occurred after a procedure not hitherto regarded as dangerous.

A boy five years old had been afflicted with hip disease for more than a year, and had been under treatment for over six months at the Samaritan Hospital. He was in comparatively good condition, was free from pain, slept and ate well, and some motion remained at the hip-joint. A cold abscess had formed on the thigh, pointing on the outer side, which was incised while the patient was under primary anæsthesia, the whole procedure lasting but a few minutes. The abscess contained about eight ounces of sero-purulent fluid. Carbolic spray was played upon the limb during the incision; the abscess was hyperdistended with a solution of carbolic acid of a strength of one to forty. This was allowed to flow out; the limb was squeezed, to force out the remaining fluid. A drainage tube was inserted, protection applied to the incision, and layers of antiseptic gauze (which had been wrung out in a solution of carbolic acid), with the mackintosh, were bandaged on to the limb, a Martin's rubber bandage being used to ensure compression. The patient recovered quickly from the ether, but in the following night was seized with obstinate vomiting, which persisted during the morning, but stopped at noon. The gauze dressing was removed and another applied, but the abscess was not syringed out. Vomiting returned in the night, and in the following morning the boy was in a feeble condition. The urine that was passed was tar color. The carbolic dressing was removed, and a cloth wet in a solution of chlorinated soda was substituted. Death took place two days later, with symptoms of collapse.

There was no diarrhoea during the illness. The temperature, twenty-four hours after the operation, was 100° F., but twenty-four hours later it fell to 96° F., returning to normal until just before death, when it rose to 102° F. The pulse was feeble throughout the whole sickness, varying from 130 to 160, and did not improve under alcoholic stimulants, the subcutaneous injection of brandy, or atropia.

Glauber's salts, mentioned as an antidote to carbolic acid, was not tried, as at the time the nature of the case was recognized stimulation seemed the only treatment indicated.

In his report of the post-mortem examination, Dr. R. H. Fitz stated that the thorax and abdomen alone were examined. An extensively diffused hæmorrhage was found in the left lung. The blood was not clotted, nor were the limits of the hæmorrhage sharply defined. The affected portion of the lung was crepitant. Both sides of the heart, especially the left, contained dark, clotted blood. The myocardium was paler than normal, its muscular fibres finely granular, the granules insoluble in acetic acid, and blackened in osmic acid.

The spleen was not enlarged nor manifestly altered.

⁴ *Lancet* i, 1881, page 429.

The kidneys were enlarged, firm, and pale. On section, the cortex was decidedly increased in volume and of a yellowish-gray color, strongly contrasting with the pale reddish-gray pyramids. The tubular regions of the cortex were indistinctly defined. The microscopic examination showed a general and extensive fatty degeneration of the epithelium of the convoluted and straight tubes. The bladder contained several drachms of yellow urine, with a slightly reddish tinge.

The liver was enlarged, firm, anæmic. On section, the surface was of a grayish-yellow color, the individual acini not readily recognized. Close inspection showed that the periphery of the lobules was more opaque than the central portion. On microscopic examination, the cells were universally found to contain large and small fat drops, the former being of relatively uniform size. An enlargement of single cells was not conspicuous.

The solitary follicles and Peyer's patches throughout the lower part of the ileum were enlarged, the former gray and somewhat translucent.

The cartilage over the greater part of the head of the left femur was eroded, and replaced by a soft, red, and translucent tissue. The synovial membrane was thickened and injected. There were no appearances observed, with or without the microscope, which indicated the presence of tubercles. A vertical section through the head of the bone disclosed red marrow, without obvious alteration of the bone tissue. The sinus descending from the hip-joint contained a small quantity of curdy pus.

The lesions of greatest importance were obviously those of the heart and kidneys. It is not unlikely that the extreme quantity of fat found in the liver owed its origin to the causes producing the fatty degeneration of the heart and kidneys. The appearances of all these organs were strikingly analogous to those met with in cases of poisoning from phosphorus or arsenic. The clinical history of the case directly suggests that the lesions found may be attributed to the toxic action of carbolic acid.

Dr. Wood's analysis of urine is as follows: Name, Case of Carbolic Acid Poisoning. From Dr. Bradford. Color, slightly smoky. Reaction, acid. Urophæin, diminished. Indican, *much increased*. Urea, increased. Uric acid, increased. Albumen, slight trace. Sugar, absent. Bile pigments, absent. Sediment, few very small fatty casts. Specific gravity, 1017. Amount of sediment, considerable. Chlorides, much diminished. Sulphates, *absent*. Earthy phosphates, increased. Alkaline phosphates, normal.

Remarks. The color deepened to a very dark brown on standing.

A very large amount of a sulpho-acid (presumably sulpho-phenylic) was shown to be present in the urine by heating with hydrochloric acid after the addition of baric chloride. The baric chloride alone produced no precipitate of sulphate of barium as in normal urine, but after boiling with hydrochloric acid, which decomposes the sulpho-acid, a very abundant precipitate was produced.

— A daily edition of the *Virginia Medical Monthly* will be issued during the four days of the session of the American Medical Association for 1881. It will give full reports of the proceedings of the general sessions and of the several sections.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

MARCH 28, 1881, DR. T. B. CURTIS presided.

PODODYNIA.

DR. T. B. CURTIS read a paper on pododynia. Vide page 316 of this JOURNAL.

DR. HODGES remarked that the pain and discomfort in the feet from which so many women suffer, especially when they are stout and past middle life, is often caused by their shoes, not only from the shoes being too tight but also too loose around the instep, allowing the foot to slip forward.

A shoe should be properly supported under the instep, as by a steel shank, which is found to be very serviceable.

A great many cases can be benefited by simply having an inside lacing to the shoe, thus drawing it tightly around the instep and allowing plenty of room elsewhere.

Another method is the introduction of an inside sole of cork covered with leather so that it can be changed from shoe to shoe and so shaped that it can give more support than the steel shank.

These devices make walking much easier and are worth trying.

Old shoes which have become saturated with perspiration, and thus a source of irritation, are among the causes of pain in the feet, and especially of burning pain.

DR. PORTER stated that he considered the pain due to stretching of the ligamentum longum plantæ or the plantar fascia from lack of proper support to the arch of the foot, most commonly noticed in fat persons, in young, adult or middle life, and in weakly children. He reported two cases, first, that of a day laborer who consulted him for excruciating pains in both soles so severe as to prevent him from working: he was recommended to replace his miserable worn-out boots with soft pliable shanks by a stout well-built pair with steel shank. The advice was followed with complete relief. A second case was of a stout, middle-aged lady, who complained that she was greatly troubled in getting about the house and up and down stairs from pains in her soles so violent as at times to cripple her and compel her to sit down frequently to rest. On the street she could walk very comfortably. It was found that she wore stout button, snugly-fitting boots on the street and low, loose slippers in the house. She was advised to discard the latter and wear a stout shoe with steel shank, with complete relief.

DR. EDES said that he had heard it mentioned that patients who had gone through with the cold water treatment for typhoid suffered from pododynia, but he himself had not noticed this sequela.

DR. GREENOUGH said that there was one point, which to him seemed a very important one, with regard to the evils of improperly-made shoes worn by women, and that was the present fashionable high-heeled shoe so generally worn, not only as a walking or dress shoe, but even as slippers. In this form of shoe the heel, which is two inches or more high, instead of supporting the heel gives support to the foot in front of the heel

almost at the arch of the instep. Its height is such that the weight of the body is thrown down upon the toes, which, by the pointed shape of the shoe at that part, are squeezed together so that an enlarged and tender great toe-joint is inevitable.

He said that for walking purposes the Waukenplast last seemed to him to be the best. The great advantage of this shaped shoe is that the inner line of the foot is straight, and the toe is broad and square, so that the great toe is not forced in, as must be the case in all rounded or pointed toed boots. Besides this the low and large heel gives a firm and solid support to that most important bearing in sustaining the weight of the body. The first pair of these shoes he had ever worn he had bought in London, and although he did not perhaps carry out the promise of the trade mark by making "five miles an hour," he found them as comfortable when he walked out of the shop as after having been worn a week. In short, there was none of that disagreeable process to be gone through which is called "breaking in." These shoes are imported by several of our dealers and imitations are also made here. Some of the latter, however, merely copy the general style, and do not reproduce what really is their main point of excellence, that is, the straight inner edge.

Dr. C. E. STEDMAN, when in the navy, used to notice the prints made on deck by the men going about in wet, bare feet. Those who had high insteps left a print like the cut. In proportion as a foot was

flat, the two marks were connected by a narrow or wide isthmus, till in a really flat foot the whole sole came down, and made its mark, as in the dotted lines.

CARBOLIC ACID POISONING.

Dr. E. H. BRADFORD reported a case of death from carbolic acid poisoning, following hyper-tension of an abscess with a carbolic acid solution. Vide page 324 of this JOURNAL.

Dr. HODGES spoke of an article written on this subject by Mr. Cheyne, Professor Lister's assistant, in which he lays particular stress on the danger of injecting wounds with carbolic acid or applications where there is a large surface of a wound exposed, insisting that this procedure should be scrupulously avoided. Dr. Hodges also remarked that the same objections existed to distending abscesses, and that he had known of serious symptoms arising from an injection of carbolic acid into the rectum.

Dr. FIELDS said, in reference to poisoning by carbolic acid, that he had recently prescribed for pruritus accompanying eczema of the lower part of the abdomen and upper part of the thighs, troubling an old gentleman, especially at night, a wash of carbolic acid of a strength of a teaspoonful of the acid to a pint of water, to be applied at bed-time. Nausea, feeble pulse, and black scanty urine had resulted.

After reporting the results of the post-mortem examination Dr. FITZ said, although numerous cases of carbolic acid poisoning have been reported within the past ten years, either the conditions are unlike those in the present instance, or the results of post-mortem

examinations have proven to be negative. At the same time there is suggestive evidence, to say the least, that an acute fatty degeneration of the heart, liver, and kidneys may result from the poisonous action of carbolic acid. French observers seem to have been familiar with such a possibility, and in Virchow's *Jahresbericht* for 1872, volume i. page 367, a case is referred to where a fatty degeneration of the renal epithelium was found.

In the *Annales d'Hygiène Publique* for 1880, page 236, the case of an adult is mentioned who died nine days after the injection of a five per cent. solution of carbolic acid into a cold abscess. The liver is described as being pale yellow and fatty, and the kidneys were also found to be fatty. In the same article is a reference to a case reported by Billroth. Death occurred six hours after washing out an abscess with a five per cent. solution of the acid. A cloudy swelling of the heart, liver, and kidneys was observed.

In the *Nouveau Dictionnaire de Médecine*, article *Phénique (acide)*, it is stated that in poisoning from carbolic acid the heart has been found flaccid and fatty, the liver and kidneys fatty, and the lungs decidedly congested, containing infarctions.

Notwithstanding these positive statements, in most of the cases recorded it is distinctly stated that the kidneys are found to be congested or pale, or show no fatty changes at all.

The indications for experimental research with regard to the toxic effects of carbolic acid are obvious, and a limited number of experiments have already been made. They do not suffice, however, to comply with the conditions met with in the case now before the society.

Sonnenburg,¹ having found traces of albumen in the urine of patients treated with carbolic acid, attributed this symptom to the treatment. He was familiar with a view that uræmia was thought to have arisen from the use of the acid, and had met with a case of severe nephritis in an apothecary's assistant, who was at the time engaged in the preparation of Lister's dressings. His experiments, made upon dogs and rabbits, were negative as regards the production of a fatty degeneration of the kidneys. He produced albuminuria in two instances, and found in all the animals used that the kidneys were hyperæmic, contained cortical hæmorrhages and blood casts.

The nature and severity of the lesions in Dr. Bradford's case, and their similarity to those resulting from poisoning by phosphorus and arsenic, the conflicting evidence to be found in the various journals and other publications, and the important practical side of the question, lead directly to the necessity of continued experiments with regard to the poisonous effects resulting from the absorption of carbolic acid. A series of such experiments are now being made by Dr. Whitney, whose results, it may be hoped, will be reported at a future meeting of the society.

Dr. GREENOUGH said that he had for the past five or six years used carbolic acid very extensively as an external application at the department for skin diseases at the Boston Dispensary. He used an ointment of the strength of one drachm of the crystallized carbolic acid to one ounce of simple cerate as a parasiticide (both animal and vegetable), and the solution K, five grains to one ounce, was the regular routine solution for cases of pruritus, etc. As far as he knew, no bad

¹ *Centralblatt für Chirurgie*, 1878, pages 751 and 759.

effects had resulted in any one of the large number of cases in which these preparations had been used. He did not know whether it was generally known that the cat family were especially susceptible to the toxicological effects of carbolic acid. He had applied a carbolic oil, one part to four or five, with a brush, to the scalp and around the ears of a full-grown healthy cat, who was suffering from *tinea tonsurans*, and in four hours she was found dead. He had been told that on the circular which accompanies one of the stronger carbolic soaps it is stated that it should not be used on cats.

DR. PORTER reported two cases of erysipelas complicated by carbolic-acid poisoning from the use of a lotion, used as a topical application, containing one part in ten of carbolic acid. In one case the buttocks and thighs were painted, and this was followed the next day by black urine, nausea, and vomiting. In the second the thighs as low as the knees seemed painted, and the next day there was black urine and nausea. In both cases two applications were made.

DR. ELLIOT said that while at the Massachusetts General Hospital he had collected thirty-two cases of poisoning by carbolic acid, and that he had noticed that patients with nephritis were more susceptible to the poison than those who had sound kidneys. Where only a small amount of carbolic acid was used it did not become apparent in the urine at first, but only after standing several hours.

Dr. Elliot also reported a case of ovariectomy where carbolic acid was used, and poisoning, with death, ensued.

DR. T. B. CURTIS said that the exceptional susceptibility to the toxic effects of carbolic acid observed by Dr. Elliot in patients with diseased kidneys was in accordance with our experience of the action of other drugs in such cases. It has long been recognized that, in chronic Bright's disease, opium and mercury were occasionally harmful and even dangerous in moderate doses. Professor Gubler, of Paris, has shown that in subjects with healthy kidneys, full doses of salicylic acid were usually well borne, a certain degree of diuresis attending the elimination of the drug; but that when the kidneys were at all impaired the administration of the acid or of its salts was apt to be followed by albuminuria, more or less marked, with diminished secretion of urine, and that under such conditions this remedy should be given cautiously. Dr. Chauvet, of Lyons, published in 1877 a paper on *The Danger of Active Drugs in Renal Diseases*, in which he set forth the evidence, afforded both by physiological experiment and by clinical observation, which showed that, in diseases of the kidneys, moderate or even small doses of certain remedies were apt to produce toxic effects. Elimination in such cases is defective, and takes place very slowly, so that drugs are liable to accumulate in the system, even when administered in the usual doses. The occasional impermeability of the kidneys, when diseased, to certain odoriferous substances, such as balsams, resin, and essences (turpentine, copaiba, etc.) has long been recognized.

APOMORPHIA.

DR. FIFIELD reported a case where a man swallowed one and a half pints of kerosene, and one third of a grain of apomorphia having been given as an emetic complete relief was obtained in a very few minutes.

DR. T. B. CURTIS said that, as he had himself not

only given but taken apomorphia, he could perhaps answer Dr. Reynold's inquiries about the properties of that drug. Apomorphia, of which the muriate is used, is one of the alkaloids of opium. It is said to act, when administered by subcutaneous injection, as a rapid, energetic, sure, and safe emetic. A one per cent. solution can be prepared for hypodermic use, containing, in each ten minims, one tenth of a grain of the salt of apomorphia, two minims of glycerine, and eight minims of distilled water. The solution, when fresh, as it should be, is of a clear, pale, emerald green. Before many days, when kept, it becomes brown, then quite black, by the precipitation of fine black particles, and is then probably unfit for use. The only fault to be found with the drug is the difficulty of preserving a solution.

The emetic effect is produced in from two to five minutes generally, the vomiting being violent and explosive, not of long duration, without nausea, though attended by vertigo, free perspiration, and a temporary feeling of great muscular debility. Emesis is followed by somnolence; but there is no subsequent collapse, such as follows the administration of tartar emetic; nor is any effect produced upon the bowels.

Emesis by apomorphia has been used and advocated either to empty the stomach, or to free the respiratory passages when obstructed. In cases of poisoning, it affords a rapid and sure means of evacuation within five minutes of its administration. In asphyxiating respiratory affections, such as croup (Sanné), acute capillary bronchitis (Riegel), catarrhal pneumonia (Jurgenson), pulmonary edema (Hertz), it has been used successfully, in patients of all ages, from infancy upwards. The dose for a child of eighteen months is stated by Dr. W. F. Duncan to be a fiftieth of a grain, while that of an adult ranges from a twentieth to a tenth, the intermediate doses being proportionate to the year of age. The speaker had once administered to himself six minims of the one per cent. solution, containing one sixteenth of a grain of the salt, and the effects produced were so powerful as to convince him that one twentieth of a grain would have been amply sufficient. The doses advised by most writers (from a third to a sixth or a tenth of a grain) seem needlessly large.

FRACTURE OF THE NOSE.

DR. FIFIELD related the case of a young gentleman aged nine years, to whom he had been called in consultation some weeks since, under the following circumstances:—

The patient had been amusing himself in company with other boys by running to and fro over the roofs of some freight cars standing in a station, jumping from one car to another. In the dusk of the approaching night he missed his leap and fell, striking the right side of the nose near the inner angle of the eye, breaking the bone into minute fragments. One of the fragments, apparently a portion of the right nasal bone, was picked out by the physician who first saw him, as it seemed entirely separated from any connection with remaining parts. From this compound comminuted fracture a gaping wound extended outwards along the lower border of the orbit whose bony rim seemed also to have sustained some fracture. Another gaping wound passed downwards in line of the nasal fracture to the cheek.

A female silver catheter passed up the right nostril showed its rounded end at the neighborhood of the internal angle of the eye, quite free from covering of

bone or other tissue. It raised in its passage the mass of bone fragments, which immediately dropped back into the nostril when the catheter was removed. The problem seemed to be not only how to elevate the comminuted bones, but to make them remain so.

A long hare lip pin, with a glass head, was taken, passed beneath the lowest adherent fragment into the nostril, then the head being slowly depressed the point was guided forwards and upwards, passing over the point where the right nasal bone was missing, and made to emerge well beneath the left eyebrow. It was a test of the goodness of Weiss's steel, for the pin bent like a bow. A bit of rubber was now slipped over the head and point of the pin.

The remaining wounds were sewed up in the ordinary way. The pin was left in place for six days, and then withdrawn, and although the wound healed by granulation the deformity is said to be remarkably slight; the open hole is firmly closed, no air passing. The bones remain in good line.

Dr. Fifield stated that the thought of treating fracture of the nose in this manner was not an original one with him. On the contrary, he wished publicly to express his obligation to Dr. Lewis D. Mason, whose article in the *Annals of the Anatomical and Surgical Society of Brooklyn*, New York, had directed his attention to this very useful proceeding, although he believed no case yet reported had been exactly like the one of which he had spoken. Dr. Mason's cases having been depressions of the nasal bones from blows which break and drive down the bridge of the nose between the nasal processes, which are in their turn fractured. In such cases the needle is passed to serve as a "tie rod" holding together the sides of the nasal arch."

Dr. Ma-on's articles at page 107, March number of the *Annals*, 1880, May, page 197, February, 1881, page 89, may be consulted with great profit, being an honor to American surgery.

Dr. Fifield's case had differed from Dr. Mason's in this, that whereas the latter had used the method to elevate the depressed and fractured bridge of the nose, the former had employed it to raise and sustain a fractured nasal process.

Dr. PORTER showed two specimens of rare disease of the testicle: one of cystic sarcoma (curling) of eight months' growth, size of a large orange, following injury; another of encysted hydrocele with exceptionally large and numerous cysts, varying from millet seed to size of a lime, containing spermatozoa.

Dr. T. B. CURTIS showed an anatomical specimen consisting of the bladder of a patient who had long suffered from retention of urine caused by obstructive hypertrophy of the prostate, and necessitating the habitual use of the catheter. In the prostatic urethra, on either side of the verumontanum, were several superposed *lacunae* or *infundibula*, varying in depth from a quarter of an inch to an inch, running backwards under the mucous membrane of the neck of the bladder, their orifices or mouths being directed forward, so as readily to receive the extremity of a straight and pointed instrument. They were sufficiently capacious to admit a number 18 (French) catheter, and one of them had been converted into a false passage opening into the bladder, in the *trigonum vesicae*, the bottom of the infundibulum having been perforated by catheterism.

These prostatic lacunae were first described by Vel-

peau¹ as liable to become the seat of false passages. They were subsequently mentioned by Professor Jarjavay, of Paris, and represented in one of the plates of his beautifully-illustrated monograph on the anatomy of the urethra,² which was handed round for inspection. Jarjavay ascribed them to an exaggerated development of the *fræna* which radiate from the posterior extremity of the verumontanum, and which are normally more or less pronounced in different subjects. Dr. Curtis had seen as many as four similar specimens in Paris, and had exhibited one before the Anatomical Society of that city, a full description being published in the records of the society.³

Dr. Curtis showed also the bladder, ureters, and kidneys of a patient whom he had seen in a desperate condition a fortnight before, with Dr. J. G. Pinkham, of Lynn, who had since made the autopsy and forwarded the specimen. The patient, aged forty-five years, had suffered for about three years from a painful chronic disease of the bladder and kidneys. He had been under exclusively homœopathic treatment, which had never included the use of a catheter nor the administration of opium in any form. There was partial retention, with a full bladder, and painful, frequent micturition, the bladder being distended with purulent, bloody, ammoniacal urine. Dr. Pinkham had already instituted the daily use of the catheter, to the great relief of the patient. There was acute pain and tenderness in the right flank. The age of the patient, the apparent absence of all of the usual causes of chronic vesical and renal disease (stricture, stone, obstructive hypertrophy of the prostate), the implication of both bladder and kidneys, together with a hard, lumpy enlargement of both epididymes and of the seminal vesicles, had led Dr. Pinkham to consider the disease to be genito-urinary tuberculous, in which diagnosis Dr. Curtis had fully concurred.

The specimen, examined by Dr. Curtis before the Society, showed unmistakable macroscopic evidence of advanced genito-urinary tuberculous, implicating the bladder, prostate, seminal vesicles, ureters, pelves, and kidneys. The prostate was almost totally destroyed, being converted into an excavation, with irregular walls. The vesical lesions were very advanced, deep-seated, and destructive; the mucous membrane had almost entirely disappeared from the internal surface of the bladder, so that the muscular layer, and in some points even the subperitoneal layer of adipose connective tissue, were exposed. The left kidney was sacculated and atrophied, with dilatation of the pelvis (pyonephrosis), its ureter being obliterated at several points. The right kidney was much less diseased; at its lower extremity there was a superficial erosion of the cortex, at a point where a large paraneplretic abscess was found. There was an ulcerative pyelitis, and a similar affection of the ureter.

—The Board of Health of New York has appointed eight physicians as lodging-house inspectors, for two weeks, with a view to discovering and preventing typhus. Seven physicians have been appointed for a month as auxiliary to the vaccinating corps. Dr. J. B. Taylor, chief of the Vaccinating Bureau, says nearly every person stricken with small-pox had never been vaccinated.

Medical and Surgical Journal.

THURSDAY, APRIL 7, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

ABDOMINAL SURGERY.¹

AMONG the abdominal viscera which may, when diseased, closely simulate ovarian dropsy, and thus occasionally place the ovariologist in the predicament of having to decide at once between the abandonment of a commenced operation, with immediate closure of the abdominal incision, or an attempt at the removal of the diseased part, is the spleen. This obviously important organ, whose functions, however, are still so far from being completely understood, is liable to become the seat of various kinds of tumors, among which are comprised several forms of cystic degeneration (serous, purulent, bloody, hydatid, and acephalocystic). The real character of these splenic cysts may remain obscure and doubtful, or wholly unrecognized and even unsuspected, until an abdominal incision has exposed the morbid growth and its attachments to view and to palpation. Such a case was that of a female, aged twenty years, from whom Péan, of Paris, in 1867, successfully removed the entire spleen, the latter being found converted into a large cyst full of a thick, viscid, brownish fluid. On the tenth day after the operation the patient was so well that it was impossible to prevent her from going out. After her recovery, which was rapid and complete, she presented absolutely no symptoms, no alteration of health, which could testify to the loss which she had undergone. This striking case of splenectomy, successfully performed in a human being, corroborates the results often obtained in *anima vili* by experimental physiologists, which go to show, according to the testimony and experience of Mosler, that the spleen is not absolutely necessary for the maintenance of life, its function after extirpation, as well as after artificially-induced atrophy, being assumed by the other lymphatic organs.

Péan's case of splenectomy, with recovery, is not the only one on record. Magdelain, who was Péan's interne, and assisted the latter in the performance of his operation, published in 1868 a paper relating this remarkable achievement of abdominal surgery, in which he got together nine cases of complete or partial removal of the spleen in traumatic cases, with hernia of the organ through an accidental abdominal wound, all of which terminated in recovery; and six cases of complete splenectomy for disease of the spleen, of which the first, performed in Italy, in 1549, by Zacurelli and Floraventi, and the second, that of

Péan, were successful; the other four, by Quittenbaum (1836), by Kuehler (1855), by Spencer Wells (1866), and by Koeberlé (1867), having each a fatal termination.

Still another category of operations, relating more or less directly to our subject, comprises the various methods for the radical cure of hernia. Numerous operations have been performed of late — especially since the general adoption of antiseptic precautions has given greater confidence in dealing with the peritoneal cavity — with a view to obliterating permanently the hernial tract in the abdominal walls. This has been accomplished by various means, namely, by effecting a closure, by inflammatory adhesion, of the peritoneal diverticulum, — ring, canal, and sac, the latter being, perhaps, removed; or by uniting firmly, by suture, the margins of the hiatus in the fibrous layer of the abdominal parietes (inguinal pillars); or by a combination of both of these procedures. In a recent and valuable paper by Dr. Reverdin, of Geneva, the various operations for the radical cure of hernia are passed in review, with a careful discussion of their merits and demerits. In many of the cases recorded — the operations having been performed by Steele, Nussbaum, Mayer, Riesel, Czerny, Schede, Socin, Annandale, Buchanan, and by Reverdin himself, — successful results have apparently been attained, but a certain lapse of time was still needed in most of these cases to show whether the integrity of the abdominal walls had really been sufficiently restored to allow artificial support by means of trusses to be permanently dispensed with. Nearly every procedure, says Reverdin, seems imperfect, in that they all effect a closure only of the external orifice of the inguinal hernial tract, leaving a more or less patent internal orifice and canal.

The last illustration of abdominal surgery, as now understood and practiced, which we shall adduce, is afforded by a recent very striking case in which Koeberlé, of Strasbourg, removed over two yards (two meters, or six feet and seven inches) of a small intestine affected with multiple strictures, the patient making a complete recovery. The subject of this operation, a young lady, aged twenty-two years, had been suffering with symptoms of chronic intestinal obstruction, referred, upon careful examination, to three different points of the small intestine, and attributed to cicatricial contraction of the bowel, though no cause for the production of such lesions could be made out. The operation was performed without the usual antiseptic precautions. An incision nearly four inches long was made in the *linea alba*, this situation for the laparotomy being mostly preferred by Koeberlé in cases of intestinal obstruction. The direct examination of the abdominal organs showed the preliminary diagnosis to have been correct; the small intestine proved to be the seat of three narrow strictures, rendering necessary the removal of a portion of gut amounting in length to two meters. The details of Koeberlé's highly ingenious operation, too numerous and minute to be reproduced here, are clearly and abundantly set forth, with illustrations, in his paper,

¹ Concluded from page 29.

published in recent numbers of the *Gazette Hebdomadaire*, of Paris. The operation lasted three and a half hours, with very little loss of blood, the patient being kept all the while under chloroform. The two ends of the divided intestine were ligated and fastened in the abdominal wound, which was partially closed by sutures, a tent of lint, moistened with a solution of carbolic acid, being inserted. The wound was covered with an open dressing, and left more or less exposed to the air. The immediate consequences were of the simplest; except on the third day, the highest temperature was 100.4° F. The patient ceased at once to suffer from the colic which had previously tortured her, and expressed herself as perfectly comfortable. She was supplied with liquid nutriment by enemata until the third day, when, peritoneal adhesions being judged to be sufficiently established, the ligated ends of the intestine were opened, an artificial anus resulting; on the twelfth day enterotomy was performed, with destruction, by compression by means of a clamp, of the spur constituted by the juxtaposed intestinal walls, and forming a septum between the stomachal and anal ends of the divided intestine. This first attempt at enterotomy proving insufficient to allow the free passage of the intestinal contents, the compression was repeated a second time, a little later, with a thoroughly satisfactory result. A month after the operation there remained only a small, very narrow fistula, which in a week more had closed. At the end of six weeks in all the recovery was completed. The patient was seen and examined by E. Boeckel, Freund, Ehrmann, Czerny, and others. The portion of intestine removed was exhibited before the Strasburg Medical Society, and examined by Recklinghausen.

Koeberlé, in his report of this case, rehearsed all the operations of a similar character which he had found recorded. Resection of cancerous portions of the large intestine had been attempted by Gussenbauer, Thiersch, Schede, Baum, Czerny, Billroth, and Bardenheuer. The removal of a cancerous pylorus had been attempted by Péan, and advocated by Nussbaum. Czerny, in April, 1880, removed two portions of the large intestine, one over four inches (eleven centimeters), the other nearly three inches (seven centimeters), long. The patient survived six months and a half, and then died of generalized carcinoma. Reyhard, of Lyons, as long ago as 1833, removed four inches (ten centimeters) of a cancerous descending colon; the two ends of the gut were sutured together, and the abdomen, opened by a lateralized laparotomy, was closed. The patient recovered from the operation, and lived six months, dying of recurrent malignant growth. The foregoing experience, mainly, afforded the precedents, on consideration of which Koeberlé was induced to attempt the daring operation briefly described above. From his own experience, in this and in other analogous cases, he deduced the following conclusions:—

(1.) Resection of the small intestine can be practiced to a considerable extent, with the possibility of removing a length of over two yards of the bowel without disturbing the digestive functions in any appreciable degree.

(2.) Under suitable conditions, resection of the intestine may be considered as a perfectly justifiable operation.

(3.) The resection may be effected: (1.) By immediately suturing the cut ends of the gut together and closing the abdominal incision. (2.) By establishing an artificial anus, to be closed by a subsequent enterotomy. (3.) By means of an incomplete suture of the gut, with the formation of an artificial anus. Of these procedures, the second and the third are the safest in the end.

(4.) Resection of intestinal strictures, fibrous and cicatricial, which are probably less uncommon than is supposed, is a means by which a radical cure can be effected. Such is also the case with regard to epitheliomatous disease of the intestine. On the other hand, resection applied to obstructing carcinomatous growths can only afford a temporary relief from the disease, which is accompanied by generalization and extension to the lymphatic glands.

(5.) By keeping the intestine closed after the operation, as was done by me, the escape of the intestinal contents can be prevented for several days, until after the formation of sufficiently firm and close adhesions. On the other hand, the abdomen is thereby prevented from emptying itself too completely after the operation, so that the patient is preserved from certain subsequent risks, such as the penetration of air or of putrid fluids into the peritoneal cavity. By nourishing the patient with foods as slightly fluid as possible the discharge of alimentary matters through the first portion of the intestine is reduced to a minimum, and the patient is less liable to become debilitated.

(6.) By introducing liquids into the system through the large intestine, by administering liquids through the rectum, water is as freely absorbed as under normal conditions, the discharge of the fluid intestinal contents is diminished, and occasions less discomfort to the patient.

Such, by way of illustration, are some of the most striking and significant achievements of recent times in the special branch of practice now known as "abdominal surgery." We say designedly *special*, for is it not clearly manifest, after full consideration of the historical facts which we have briefly passed in review, that a special kind and degree of knowledge and skill, attainable only by long experience, are requisite to enable the surgeon to practice ovariectomy, as well as the kindred operations involving the exposure of the peritoneal cavity, with the necessary boldness, confidence, and security by which only such procedures are rendered beneficial and legitimate? To sustain this view, to emphasize the need of a special apprenticeship and of a long and thorough training in the art of abdominal surgery, it is only necessary to point to the constantly increasing skill and success attained by Mr. Spencer Wells, and made evident by the steady diminution of his rates of mortality in ovariectomy. McDowell himself, at the outset, when he was striving to make ovariectomy a boon to humanity, clearly recognized the need of special qualifications for its performance, and foresaw, as Spencer Wells once took occasion to recall, "the dangers of its abuse from rash and indiscriminate rivalry amongst his followers." His emphatic warning against such abuse of the operation was quoted with approval by Spencer Wells, as follows: "I think my description of the mode of operating, and of the anatomy of the parts concerned, clear enough to enable any good anatomist, possessing the judgment requisite for a surgeon, to operate with safety. I hope no operator of any other description may ever attempt it. It is my most ardent wish that this operation may remain to the mechanical surgeon forever incomprehensible. Such have been the bane of the science, intruding themselves into the ranks of the profession with no other qualifications but boldness in undertaking, ignorance of their responsibility, and indifference to the lives of their patients; pro-

ceeding according to the special dictate of some author as mechanical as themselves, they cut and tear with fearless indifference, utterly incapable of exercising any judgment of their own in cases of emergency, and sometimes without possessing the slightest knowledge of the anatomy of the parts concerned. The preposterous and injurious attempts of such pretenders can seldom fail to prove destructive to the patients and disgraceful to the science." Finally, if additional corroboration of our position were called for, it would suffice for us to recall the rare and praiseworthy frankness, modesty, and abnegation displayed by Mr. Erichsen, who, albeit one of the foremost surgeons of our time, has not hesitated, as we have shown, to avow openly and plainly his own incompetence to perform the operation out of which the *specialty* of abdominal surgery has grown, and by the practice of which alone it is to be attained.

BUCHANAN THE DIPLOMATIST AS A CONFESSOR.

THE worthy Buchanan, of diploma notoriety, is now bending all the energies of his active nature to confessing, if the account lately published in the *Philadelphia Record* is to be accepted as authentic. He is evidently determined to gratify the authorities by painting with a big brush a picture more beautiful than nature herself, and is prepared to relish the rôle of Sampson after having tried that of a Philistine. As Sampson there is apparently no medical temple so sacred but that he is eager to bring it down. If there is one thing, however, for which he seems to have a real genuine contempt it is a small diploma without much parchment.

The following are some of the most picturesque confessions:—

FOREIGN DIPLOMAS.

"I have been offered the degrees from all the institutions in Great Britain, but I never accepted one: I would not pay the expressage on them. Van der Vyver¹ has written to me that if any one wanted the title of Count or Countess, or Duke or anything, he could supply it. That furthermore, he could, for a consideration, create a man a bishop or anything.

"In Scotland there are four Universities—Edinburgh, Aberdeen, St. Andrews, and Glasgow. All teach theology, arts, law, medicine, and their collateral branches. Edinburgh in 1845 publicly advertised that it would sell one thousand diplomas at \$50 each. In 1847–8–9 I could have bought them while attending Glasgow. They were around thick. I cannot specify a case, although Sturnam said I could have all I wanted if the price would be paid.

"Besides those four bodies there are the Royal Colleges of Surgeons at Edinburgh and Glasgow. These bodies confer M. D. as well as well as their title F. R. S., E.L., etc. Those societies to the uninitiated seem great, but they are simply club houses. The Medical act has injured them very much. These are all incorporated bodies. The Andersonian University has no corporate power.

"The Dublin University is really the only school in Ireland that deserves the name of being such, and prior to 1857 it was like the others.

"England has a large number of medical schools, besides the two great universities, Cambridge and Oxford. There are also Royal Societies, but the same spirit haunts them all—they will sell degrees.

"Sturnam, Sayre, and Van der Vyver² have offered to sell me their degrees, but no sensible, practical American will pay their prices. The London University is the great medical degree depot. Admission to the various Royal Societies is easy. They

¹ A prominent diploma broker.

² Diploma brokers.

will not refuse a £5. Their certificate or diploma is about six by twelve inches!

"The German Universities are more celebrated than the English. Every school in Germany did it freely and openly for about fifteen years. I was acquainted with a number of colored men in this city who had bought them. I might enumerate Rosell, Davis, Clarke, all dead, and I know of men all over the country. I have often thought that there are at least 5000 out—probably double that number. It seemed to be done direct, inclosing the cash and getting the return. The diplomas are quite small! I have heard little of this traffic during the last twelve years. I have often been informed that all the degrees of European schools have been manufactured here. As far back as 1862 I saw in the possession of Fenton, a Canadian, a roll of European diplomas. Chicago has been mentioned as the depot. Stickney went there after them, I know, but he said they were so frightened he could do nothing with them. In the possession of Mummy I counted eleven German and Royal Society of London diplomas."

"Rev. George Sexton, of London, who was prominent in the British Medical Reform Association, to whom I sold diplomas in 1874, is a European agent of Fields. Sexton commenced his career as a missionary, then became a lecturer for Kahn, and now is the agent for the Anthropological University of St. Louis.

ANTHROPOLOGICAL UNIVERSITY OF ST. LOUIS.

"Fields, Sexton, Alford, and Thrasher have an organization as perfect as the Catholic Church. They have penetrated every city of America and Great Britain with their agencies. The Eclectic is not popular, and does not sell well, but the University of Anthropology goes off like hot cakes. I have understood I could buy five hundred of its diplomas in bulk at any time. They deal largely. Alford and Sturnam have approached me, but I never answered their communications.

"The Scotch ministers take to these university degrees like a set of hungry wolves. They will not investigate. They have the degree mania badly. Fully twenty thousand diplomas of this university have been sold in Europe to ministers, doctors, and teachers."

Buchanan was secretary of the concern at its organization. Alford was a lecturer at Buchanan's college, and the American University then embraced the Anthropological University as its theological branch.

Concerning the New England University he says: "Henry C. Stickney, who runs the concern, told me he had sold thousands of these diplomas throughout Europe. They were worthless."

The Eclectic Medical of Georgia was the only eclectic college in the country which was recognized by Buchanan as in communion with his National Medical Association. Fishblatt, who is credited as a professor of dermatology in that institution, was, Buchanan says, in an arrangement with Professor Polk to sell eclectic diplomas.

DRUID UNIVERSITY.

"This concern is chartered by the State of New York, and extends all over the United States. Drs. Brown and Davies, of Athens, Maine, are owners of the charter, stone, and seal. They adhere to Culpepper on materia medica. Davies was originally an Episcopal clergyman, but turned to medicine, and took our diploma. The Druids are confined to the Welsh. The Druids implored me, two years ago, to abandon our State charter, and begin under their auspices, but I was troubled with my head, and would not go in."

It is natural that those who wish to succeed to Buchanan's honors and emoluments should find it necessary, as well as politic, to make a little more pretense of giving medical instruction. The market must be pretty well supplied with mere parchment, according to the confessor's estimates that twenty thousand bogus diplomas are current in the United States, and forty thousand more in Europe, though we are afraid his figures are certainly not more than "fractionally accurate."

Buchanan himself seems to have a certain amount of respect for state examination and registration as insuring a tolerably definite standard. His experience should entitle his opinion on this point to confidence.

MEDICAL NOTES.

— Dr. Isaac Ray, a distinguished physician and author, died in Philadelphia on March 31st, in the seventy-fifth year of his age. Dr. Ray was born in Beverly, Mass., graduated at Bowdoin College in 1827, and studied medicine with Dr. Shattuck, of Boston, and at the Harvard Medical College. He first practiced in Portland, Me., and later removed to Eastport. Dr. Ray was appointed in 1841 to the position of superintendent of the State Hospital for the Insane at Augusta. From there he removed to Providence in 1846, to superintend the construction of the building for the Butler Hospital, of which he subsequently had charge. He resigned his position at Providence in January, 1867, and removed to Philadelphia. As a medical writer on subjects connected with insanity, and as President of the Society of the American Superintendents of Insane Asylums he was widely known and greatly esteemed.

— The *Lancet* speaks in terms of the highest praise of the experience of the Guardians of the Cork Union in boarding out pauper children. It has proved in their hands a most excellent method of dealing with one of the most difficult of social problems, and contrasts favorably with the workhouse plan. It is cheaper, the children are remarkably healthy and happy, and in a large majority of cases are adopted by the foster parents. The foster parent is appointed on the recommendation of local clergymen, and is generally either a small farmer or a well-to-do laborer. From 1862 to the present there were 650 children removed from the workhouse and boarded out in several favorable districts, seaside or mountainous, in which the Union abounds. Of this number 209 are at present boarded out, and 417 have been adopted by their foster parents, and are going on well, 20 have died, and 1 have returned to the workhouse, and are now ready to go out to service. Here are 417 children at the age of thirteen, on the application of their foster parents, taken off the roll of pauperism to start fair in the world. Much importance is attached by the committee to the supervision of relieving officers, assisted by clergymen and ladies, and to the periodical reports of the dispensary medical officers on the health of the children. This report of the boarding-out committee is worthy of the serious attention of all guardians of the poor.

Recent Literature.

A Text-Book of Human Physiology. By AUSTIN FLINT, JR., M. D. Third Edition: D. Appleton & Co. 1881.

Professor Flint may well be gratified with the flattering success of his text-book, which is entering upon its third edition within six years of its first appearance. While we congratulate the author upon this fact, and while we recognize the great pains and labor he has bestowed upon the book, we must sincerely regret the numerous glaring faults of omission of which the author is guilty. Professor Flint has often been severely criticised for attempting to portray the recent

state of physiological science while ignoring in an inexplicable manner the work and writings of his German colleagues. Some improvement in this respect may be noticed in this third edition, where we do occasionally meet the familiar name of some living German physiologist. Yet, taken as a whole, the book is mainly a history of the state of physiology in France twenty years ago rather than the expression of the achievements and hopes of modern physiology.

Perhaps the portion of the book wherein the omissions are most conspicuous is in the chapters upon secretion and digestion. On reading these chapters we are carried back to the times and triumphs of Bernard, but we search in vain for the names of Heidenhain, Kühne, Brücke, Luchsinger, Nawrocki, Adamkiewicz, Klemensiewicz, and a score of others whose works have thrown rays of light upon so many dark places. In the description of the proteolytic action of the pancreatic juice nothing is said regarding trypsin, and no mention is made of the brilliant experiments of Heidenhain and Kühne, by which the metabolic processes in the gland cells are exposed to our very gaze under the microscope. In casually referring to the fact that the activity of sweat glands is modified by nerve influence, no account or even hint is given of the exhaustive researches which have traced the course of the individual nerve fibres from the sweat glands back to their centres in the brain, and which have revealed the wonderful trophic influence of these nerves.

Again, in speaking of coagulation of the blood, while much space is devoted to a rehearsal of several old and exploded theories, the elaborate investigations of Schmidt and his followers are dismissed in one paragraph, with the supposition that fibrinogen and fibrinoplastin are products of decomposition of plasmin. In this connection we would correct an inaccuracy of the author where he says: "It is true that the so-called *fibrinogen* added to the liquid of hydrocele or other serosities not spontaneously coagulable produces coagulation." Hydrocele fluid already contains *fibrinogen*, and it is necessary to add *fibrinoplastin* in order to produce coagulation.

This list might be indefinitely extended, but enough has been said to show the reason for our condemnation of the book in its claim to be a fair or proper representation of the science of physiology. Lack of space cannot be urged in plea for its deficiencies, because the book is confessedly a full treatise, and the author does not consider it "desirable to omit any subject properly belonging to human physiology." It may be objected that some points have been omitted by reason of their uncertainty and lack of substantial proof, but we could mention scores of indubitable facts, veritable corner-stones of physiological science, which are apparently not dreamed of in Professor Flint's philosophy. A teacher of physiology should be no mere chronicler of past events, nor need he waste his time with mere theories and multiplicity of detail; but he should endeavor, in as concise and graphic a manner as possible, to spread before his readers a complete map of the work as it actually exists, and he should strive to point out those avenues of future development which lead to more remote and richer fields.

We are disappointed in this book, and we think the warm reception which it has already received from the profession merits a more complete and more comprehensive description of the present state of physiology.

G. M. G.

The Surgery, Surgical Pathology, and Surgical Anatomy of the Female Pelvic Organs. By HENRY SAVAGE, M. D., London. Third edition, revised and greatly extended. New York: William Wood & Co. 1880.

The physician who has not been personally familiar with the English editions of Dr. Savage's book, judging only of its great worth by the position accorded the author in so much of our standard gynecological literature, as the highest authority in the surgical anatomy of the female pelvic organs, must have longed to possess the work. The elaborate and beautiful plates in the English editions necessarily made the book expensive, and, as a consequence, its ownership has been comparatively limited.

It may now, however, be found in Wood's Library, where its appearance was a most grateful surprise. Its plates have lost their coloring; but they remain, as they have ever been, the most instructive and truthful of any with which we are familiar. With the thorough revision of the text and the thirty-six additional wood-cuts, the book cannot fail to be one of the special prizes of this library.

A Practical Treatise on the Diseases of Women. By T. GAILLARD THOMAS, M. D. Philadelphia: Henry C. Lea's Son & Co. 1880.

The determination of the author to keep his book foremost in the rank of works on gynecology is most gratifying. Recognizing the fact that this can only be accomplished by frequent and thorough revision, he has spared no pains to make the present edition more desirable even than the previous one. For in this we see not only our old friend in new and tasteful attire, but on carefully scanning its pages we find evidences of the enlarged experience of the author together with the results of his ingenuity and skill, especially in the treatment of malpositions of the uterus by mechanical appliances.

The volume is by no means the outgrowth of one man's investigation and labor, but is in every sense a thorough treatise on the Diseases of Women; and it is so systematically arranged and carefully indexed that, as a book of reference to the busy practitioner, it is unequalled. We know of no other gynecological author who can so effectually rescue from neglect or forgetfulness an important principle or method of treatment which has been once given to the profession. Seeing its value himself, he so positively asserts its claims, and so forcibly presents its merits, that its recognition and adoption become established facts.

We are glad to see the increased importance ascribed in the present edition to certain subjects, notable among which are Atresia of the Genital Tract and Laceration of the Cervix Uteri, each having a special chapter, well illustrated by diagrams, devoted to its consideration. The pathology of the book, heretofore its weak point, has also received due attention, and the advance thus inaugurated will doubtless in some future edition lead on to preëminence. It is to be regretted that more space is not allotted to the subject of development. Comparatively little has been written upon it, the volume before us containing more than its predecessors, and more than most kindred treatises, and the task of working up the subject thoroughly would

be most arduous; yet we know of no one who could so well accomplish it as Dr. Thomas, either personally or by guiding some one else.

The rapid progress made in gynecology becomes very noticeable if we compare the early editions of this work with the present one; and when we remember that it is but twelve years since the first one was issued we are the more surprised that our views should have changed so much. Take, for example, the one subject of Ulceration of the Os Uteri, to which ten or fifteen pages were devoted then. Now, except as the result of syphilitic or malignant disease, it is not mentioned. Dysmenorrhœa, Menorrhagia, Amenorrhœa, and Leucorrhœa are sharing the same fate; and we hope in his next revision the author will cast them out entirely, treating them purely as symptoms under the heads of the conditions which give rise to them. The present method can but mislead many in the profession to the establishment of a course of treatment designed to relieve a symptom; whereas they will then be guided to search after and attack the cause of the symptom.

Dictionnaire Annuel des Progres des Sciences et Institutions Médicales. Par M. P. GARNIER. Seizième année. 1880.

With its usual promptness this dictionary, now in its sixteenth year, comes to hand. The opening words of the introduction intimate that if the value of the medical productions for 1880 equals their abundance and variety, the year will certainly be one of the most propitious and fruitful in the art of healing. The grandest discovery of the year, if time confirms its value, is the inoculation of animals with the attenuated culture-liquid of the bacteria of charbon to render them insusceptible to the disease. The author regrets that the younger physicians of the present day, in their zeal for the new forms of science, are inclined to neglect clinical observations. A résumé of matters of interest in therapeutics, surgery, pathology, obstetrics, and the special branches is given in the introduction, and the body of the work — nearly 600 pages — is devoted to articles on many and varied subjects arranged in alphabetical order.

The author is somewhat inclined to disparage the work of German physicians, but that of the profession of other nationalities is well presented.

On the Bile, Jaundice, and Bilious Diseases. By J. WICKHAM LEGG, F. R. C. P. S., etc. New York: D. Appleton & Co. 1880.

This work is devoted, as the preface informs us, to that office of the liver, which, for two hundred years, was the only one allowed by physiologists, — that is, the secretion of bile. The first chapters treat of the chemistry and physiology of the bile; the latter, the author confesses, being still surrounded by a darkness almost Egyptian; then follow several chapters dealing with the phenomena caused by an obstruction to the discharge of the bile into the intestine, and others giving an account of certain species of jaundice where an obstruction to the discharge of the bile cannot at once, and without trouble, be discovered after death. The author omits any account of gall-stones, feeling that the

space required for anything like a full discussion of the phenomena caused by these bodies would exceed the limits prescribed for this work.

In the last chapter the meaning of "bilious diseases" is specially considered, and we heartily sympathize with the writer's proposition that the word "bilious" should no longer be used as an adjective to diseases, though exactly how a great many good people will console themselves should they be at length deprived of their present use of the word, we do not exactly foresee.

The book is a learned one, and in its 700 octavo pages presents a repository of past and present knowledge concerning the subjects of which it treats. It is a handsome volume, with large, clear type and several beautiful chromo-lithographic illustrations.

Miscellany.

THE EYE IN TRANCE AND OTHER SYMPTOMS.

MR. EDITOR, — In your report of my lecture on Trance, which was in the main correct and well stated, there was one error of importance.

The pupil reacts to the light even when there is anaesthesia of the eye: this fact I have observed in all my cases thus far; and it is a fact that has an interesting medico-legal bearing.

I have just returned from a visit to the case of spontaneous trance in Lehigh County poorhouse; and in that case, where the trance has existed for seven weeks without interruption, the pupils still react to the light, and, as usual in cases of trance, other automatic processes of the body go on as in health.

In regard to the local analgesia or abolition of sensation of pain of which your reporter speaks it should be stated that the area of analgesia was restricted to the *point where the needle was inserted*, instead of a space of the size of a dollar; and at the same time the whole half of the body on that side was somewhat analgesic and the other half of the body was hyperaesthetic.

In regard to the artificial induction of aphasia and agraphia in the trance orators it should be added that pressure on any part of the body, if the pressure or shock be sufficiently strong, will produce precisely the same effects as touching the back of the neck; indeed, in a virgin case — one that has not been previously experimented on — sudden and firm pressure over the ribs has, in my private experiments, stopped a trance speaker, and the same pressure in the same place has set him speaking again.

The points at the back of the neck and over the lower jaw seem, in some cases at least, to be more sensitive to reflex irritation of this kind and are certainly more convenient to operate on in a lecture. I do not regard them as centres, but only as more susceptible to irritation while the subject is in trance; the difference in this respect between these points and other parts of the body being of degree rather than of kind.

I may perhaps add here that in my private experiments, which I have been carrying on quite frequently during the past four months, I have lately been able to demonstrate that the sense of vertigo can be entirely or nearly abolished in the trance state. The experiments in this line were made at the suggestion of my friend, Dr. William James, of Harvard College, and

the method of conducting the experiments was suggested by him. The plan was to make the subject whirl rapidly round in a swing so suspended that it could be twisted up and allowed to untwist. Furthermore I have convinced myself by many experiments that the color-blindness in these subjects, whether in one eye or both eyes, is real and not feigned.

GEORGE M. BEARD.

13 WEST TWENTY-NINTH STREET, NEW YORK.

MOUTH WASHES IN ILLNESS.

MR. EDITOR, — A severe strain upon the system is often accompanied by increased decay of the teeth. For example, one sees this increased decay even during the physiological process of reproduction, after a period of financial depression, during the protracted illness of some dear relation, after a sojourn in foreign countries, and during recovery from acute exhausting diseases.

As in some of these conditions the general practitioner is likely to have the patient under his care I wish to suggest the importance of prescribing for the teeth as well as for the general condition.

No doubt in many acute cases danger to life may overshadow minor considerations, yet this is usually for a limited period.

Among the more immediate causes of this decay diminished power of resistance in the teeth ranks first; others are vitiated oral secretions, neglect of the ordinary mechanical means of cleaning, thus allowing food and the waste products of the mouth to accumulate. Aside from constitutional treatment to build up the system, the indications for local treatment are increased care in cleaning the teeth, together with the use of suitable washes to prevent decomposition, neutralize acidity, and destroy germs if these have any part in decay. As in acute prostrating diseases the patient is too weak to brush the teeth, reliance is to be placed in the frequent use of a mouth wash. Nor will any difficulty be found in this, as even in severe prostration the muscles about the mouth remain strong.

As examples of mouth washes the following are given. The use of carbolic acid alone, or in combination with an alkali, can seldom be resorted to, because patients associate it with unpleasant places. Benzoic acid, thymol,¹ eucalyptus oil, or boracic acid, answer the purpose, and some one of them is generally agreeable to the patient.

- | | | |
|-------------------------------|-----------------|----|
| 1. ℞ Sodæ boratis | 15 grams. | |
| Thymol | 200 milligrams. | |
| Aque | 1000 grams. | M. |
| 2. ℞ Sodæ boratis | 15 grams. | |
| Olei eucalypti | 2 grams. | |
| Magnesiæ carbonatis | 4 grams. | |
| Aque | 1000 grams. | M. |

Rub the oil with the magnesia, add the water gradually, having dissolved the borax in it, then filter and mark the filtrate Mouth Wash.

The patient should hold the wash in the mouth for at least a minute, forcing it constantly in and out through the spaces between the teeth, to bring the fluid in contact with the points of decay, changing their reaction from acid to alkaline, and washing out the *débris* collected about the necks of the teeth and in the spaces between them.

WILLIAM HERBERT ROLLINS.

¹ Suggested by Dr. Charles H. Williams.

BREAST-SUPPORTER.

MR. EDITOR,—There appeared in your issue of March 17th a plate representing a breast-supporter which was in use in the Boston Lying-In Hospital. Since that time quite a number of inquiries have reached the writer concerning the apparatus, and it may be that a word of description will not prove uninteresting to your readers.

The instrument was first devised at the Lying-In Hospital in the month of December last, to take the place of the old-fashioned bandages and towels that had been in use to support over-distended and painful breasts, especially in cases where an abscess was supposed to be threatening. The chief objection found to the use of the bandages lay in the difficulty of proper application, all the turns and folds having to be sewed to prevent slipping, and great care being necessary to prevent such pressure upon the painful gland as to make a bad matter worse. Add to this the fact that no matter how much care is exercised in adjusting, it will roll into cords which are especially uncomfortable to the patient, and it will become wet with milk, thereby necessitating renewal.

To obviate some of these difficulties the above apparatus was produced and was found to do more than had been hoped for it. Applying the pressure evenly and gently upon the sides of the breast merely, it

thereby lifts them from the axillary space toward the median line of the body, thus producing the desired effect and affording the greatest relief. Briefly stated, the advantages of the instrument are cheapness, ease of application, and efficiency. Its chief disadvantage is that it can only be worn in the recumbent position, but when it is remembered that the conditions calling for the use of such an apparatus rarely present themselves after the first two weeks following parturition, during which time the patient will, of course, keep her bed, it will be seen that the objection is not a serious one.

Messrs Leach & Green have consented to make the apparatus and furnish it to the profession at the lowest possible price. Yours very truly, R. A. KINGMAN.

BOSTON, 13 BERNBORGH PLACE, March 31, 1881.

WANTED: A SOLUTION OF MORPHIA.

MR. EDITOR,—Will some of your readers give in the JOURNAL a recipe for a solution of morphia or one of its salts, suitable for hypodermic use, which will keep without deterioration? Magendie's solution in a short time develops a penicillium-like growth,—at expense of the alkaloid, I suspect.

Respectfully, QUERIST.

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 26, 1881.

Deaths reported 2917 (no return from New Haven); 1092 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 621, consumption 417, lung diseases 415, diphtheria and croup 190, scarlet fever 103, cerebro-spinal meningitis 70, small-pox 59, diarrhoeal diseases 52, typhoid fever 37, measles 29, malarial fevers 27, erysipelas 24, whooping-cough 15, puerperal fever 12, typhus fever three. From *small pox*, Philadelphia 43, New York 10, Chicago four, Brooklyn and Pittsburgh one. From *diarrhoeal diseases*, New York 17, Chicago six, Boston and New Orleans five, Philadelphia four, Brooklyn and Baltimore three, District of Columbia and Pittsburgh two, St. Louis, Cincinnati, Fall River, Salem, and Malden one. From *typhoid fever*, New York nine, Philadelphia eight, Baltimore three, Chicago, St. Louis, New Orleans, Lowell and Lawrence two, Boston, District of Columbia, Pittsburgh, Milwaukee, Somerville, Chicopee, and Palmer one. From *measles*, New York nine, Boston six, Baltimore, Cincinnati, and Gloucester two, Philadelphia, Chicago, St. Louis, Nashville, Worcester, Somerville, Newton, and North Adams one. From *malarial fevers*, Brooklyn and New Orleans eight, St. Louis five, Philadelphia three, Chicago, Pittsburgh, and Charleston one. From *erysipelas*, New York seven, Philadelphia, Brooklyn, and Chicago three, New Orleans two, Boston, St. Louis, Cincinnati, Pittsburgh, Charleston, and Fall River one. From *whooping-cough*, New York five, Boston and St. Louis two, Philadelphia, Chicago, Baltimore, Cincinnati, Pittsburgh, and Providence one. From *puerperal fever*, Philadelphia, Boston, and St. Louis two, Brooklyn, Chicago, District of Columbia, Pittsburgh, Milwaukee, and Taunton one. From *typhus fever*, New York three. The mortality from cerebro-spinal

meningitis has increased from 57 for the week ending March 19th to 70.

Eleven cases of small-pox were reported in Brooklyn, 14 in Chicago, two in Pittsburgh; scarlet fever 28, diphtheria eight in Milwaukee.

In 46 cities and towns of Massachusetts, with a population of 1,141,363 (population of the State 1,783,086), the total death-rate for the week was 22.20, against 20.19 and 20.44 for the previous two weeks.

For the week ending March 5th, in 149 German cities and towns, with an estimated population of 7,871,797, the death-rate was 25.8. Deaths reported 3901; 1803 under five: pulmonary consumption 589, acute diseases of the respiratory organs 412, croup and diphtheria 163, scarlet fever 82, whooping-cough 65, typhoid fever 59, measles and röteln 42, puerperal fever 16, small-pox (Königsberg five, Lübeck, Tilsit, Bremen, Aachen two) 12, typhus fever (Posen) one. The death-rates ranged from 17.5 in Frankfurt a. M. to 35.6 in Cassel; Königsberg 28.4; Breslau 35.4; Munich 33.2; Dresden 24.1; Berlin 22.8; Leipzig 19.5; Hamburg 24.1; Hanover 17.8; Bremen 19; Cologne 24.4; Strassburg 28.4.

For the week ending March 12th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 25. Deaths reported 3357; acute diseases of the respiratory organs 304, whooping-cough 84, scarlet fever 63, small-pox (London 58) 59, fever 33, measles 31, diarrhoea 29, diphtheria 12. The death-rates ranged from 15.8 in Brighton to 28.8 in Manchester: Bristol 20.9; Birmingham 21.2; London 22.4; Sheffield 23.2; Liverpool 26.7; Leeds 27.8; Manchester 28.8. In Edinburgh 20.3; Glasgow 24.6; Dublin 33.8.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 26, 1881, TO APRIL 1, 1881.

Browns, H. E., major and surgeon. Promoted from assistant surgeon, *via* Otis deceased.

Woodruff, E., captain and assistant surgeon. Relieved from duty in Department of Texas, to proceed to New York city, and by letter report arrival to the surgeon-general. S. O. 72, A. G. O., March 30, 1881.

Ainsworth, F. C., captain and assistant surgeon. Now awaiting orders in New York city, to report in person to the commanding general, Department of Texas, for assignment to duty. S. O. 72, C. S., A. G. O.

Worthington, J. C., captain and assistant surgeon. Now on leave of absence, to report in person to the commanding general, Department of the East, for assignment to duty. S. O. 72, C. S., A. G. O.

Surgens E. J. DOERING, United States Marine Hospital Service, lately in charge of the hospital at Portland, Me., has tendered his resignation to the secretary of the treasury, and will return to private practice in Chicago.

A CORRECTION.

MR. EDITOR.—Your types have made me responsible for some rather peculiar views on pathology in the last sentence of my notice of Dr. Warren's work on the *Columba Adiposa*. I am

made to say "it is through these canals that the pus forms a carbuncle," but I said that "through them the pus from a carbuncle and the elements of morbid growths make their way to the surface." Perhaps this is worth correcting. I said nothing when in a recent notice the types changed "authorities" into "abscesses."

CLINICAL LECTURE.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, OCTOBER 13, 1880.

BY PROF. A. JACOBI.

CASE I. You will remember this interesting case, gentlemen, at least those of you who were present at this clinic on Wednesday last. (The case was that of the rachitic child, aged two years, who had at various times been the subject of numerous complicated fractures of the arms, leg, thigh, etc.) There is not a single one of these fractures which has healed kindly. You remember what I said about such fractures in children, — that they are rare, and that these fractures are not complete, but ought rather to be called *infractions*. Rachitical bones rarely fracture in their entire mass. The periosteum being thicker than natural holds them together, and acts as a splint, so that often all that is necessary in these infractions of rachitical bones is to bend them back again, and then retain them in their normal position. That is the sort of fracture that has taken place in this case. You will remember that I spoke of the hereditary element here, and the probability that the rachitis in this child was due to syphilis. I mentioned the fact that George Wegner first discovered that the softening of the costal ends of the ribs was due to syphilis, and that we have in this child's thorax, but although that is so, yet the bone itself does not show whether the softening is due to rachitis or syphilis. As far as this case goes we have had the child on general anti-rachitical treatment, and it is certainly doing well. We have told the woman how to feed the child, and have given it ten drops of the syrup of the iodide of iron three times a day. As the bones of each humeri have united at a vicious angle, I should propose, when the child is older and stronger, to refracture them, and get them to heal in better position. At present, however, such a procedure is out of the question, as the child is not in a condition for it.

The next case is that of H. R., aged thirteen months. He is the youngest of four children, one of whom died in a convulsion at the age of three months. The other two, however, are living and in good health. The mother says that during her last pregnancy her then youngest child had a great number of attacks of general convulsions, occurring at irregular intervals, preceded by nausea and vomiting, and followed by high fever, but these attacks have not recurred since the child's third year. The child's mother married her first cousin, but both she and her husband are healthy. This child, which is brought here for treatment, was born at term, but was very feeble at birth. It began to smile when four months old, has cut no teeth, has never had convulsions. Until it was three months old its bowels never moved without an injection, but have been regular ever since. The muscular system is in a state of chronic contraction, and a letter from the physician who has been attending the child states that he suspects that the trouble is chronic hydrocephalus. Let us take the measurement of the head. From the occipital protuberance to the base of the nose the head measures forty-one centimeters, that is, about sixteen and one half inches, and from one mastoid process to the other, twenty-eight centimeters, or about eleven

inches. That would not be a very large head. The head of the new-born child measures from fourteen to fifteen inches, nearer fourteen inches in girls, fifteen inches in boys. A measurement, then, of sixteen and one half inches only points to an increase in size of from an inch to an inch and a half, which is not too much. I should therefore think it unlikely that the child is the subject of extensive effusion, but you remember that the child has been suffering from constipation in the early months of its life. There are but three universal causes for constipation in the very young, namely, first, improper feeding; second, a peculiar anatomical condition of the colon, which is very long in proportion to the rest of the canal, and bends back on itself, so that, as a result of this recurvature, there are two or three sigmoid flexures in which the feces accumulate, and being detained there get dry and hard. This peculiar condition cannot be cured. It will only get well when the child is five or six years old, the process of growth bringing the intestines to their normal proportions, and the sigmoid flexures becoming simplified. The third cause for constipation is debility of the muscular layer of the intestine. Children born at the seventh month of utero-gestation are subject to this form of constipation, because their muscular system has not yet developed its proper strength. A fourth cause for constipation is intestinal muscular debility dependent on rachitis. One of the first symptoms of rachitis is this muscular debility, not only affecting the voluntary muscles, but the involuntary as well, and it is this form of constipation which this child has suffered from, in all probability, but are there any other symptoms of rachitis here present? There is thickening of the epiphyses of the long bones. Both the ulna and radius show signs of rachitical swelling. The head is square, more quadrilateral than it ought to be. A child suffering from rachitis, especially when it is developed early, will often suffer from brain symptoms. Just as the rachitical swelling takes place in the periosteum of the bones, in the same manner the dura and pia mater may become the seat of softening, and effusion take place, giving rise to cerebral symptoms. The paralysis of the larynx which sometimes appears in this disease is due to a rachitical softening of the cranial bones and effusion beneath the surface of the pia mater. If that is so, and if this child has had brain symptoms, then it is very likely that they were due to rachitis. We have no evidence, certainly, of hydrocephalus, for the head is not very large, and the brain symptoms are no doubt dependent on a very slight softening of the dura and pia mater and a consequent effusion. I believe that if sufficient time is given us to change the condition of the child, — that is, if no severe form of brain symptoms occur — if we can have six or seven weeks' time, the prognosis is favorable. For in that length of time we may hope that the administration of the iodide of iron, the hypophosphite salts, and plenty of good food, beef, etc., may bring about a changed condition, although convulsions may take place at any time and terminate the case. The child should have plenty of air. Such a child will never get well unless it has plenty of oxygen. I have seen cases where the children have had convulsions continually, which, however, ceased immediately when the patients were given a full supply of oxygen. It is more important that they should have fresh air at night than in the day-time. Forty-nine out of fifty bedrooms are simply nasty in the morning from lack

of ventilation. See, then, that the children breathe pure air at night. Keep the windows open. In this case I shall rely on anti-rachitic treatment. I should not feel justified in giving iodide of potassium. I think that the syrup of the iodide of iron would be much better. Let the child bathe twice a day in warm water, not cold, so as to re-establish the cutaneous (?) circulation, its head being supported on a pillow while in the bath.

CASE II. The appearance of this child strikes you at once as being peculiar. You notice the small size of the head and its peculiar shape. It is four months old, its mother says, yet did not begin to smile until six weeks ago. It nurses well, but cries a good deal, and does not sleep well. The mother has another child two years and a half old, who is perfectly healthy. She has had no miscarriages, and there is no family history of consanguinity. Let us measure the child's head, and see how it compares in size to a normal skull of the same age. The circumference of the head is thirty-one centimeters (twelve and one half inches); from occipital protuberance to base of nose nineteen centimeters (seven and one half inches), and from ear to ear seventeen and five tenths centimeters (seven inches). The occipital portion of the head is well developed, but the frontal region recedes greatly; the anterior fontanelle is slightly open. At the age of four months this baby's head ought to have a circumference of sixteen inches at least. The head of a newborn child ought to measure fifteen inches, but this child measures only twelve and one half inches round the head, which is about the same dimension as the head of a seven months' fetus. What is wanting here, then? The frontal lobes, in all probability, although these might be pushed back to such an extent as to cover the middle lobes, and it might be that the posterior lobes were wanting.

Why is it that this head has not grown as it ought to have done? Premature ossification of the cranial bones might be the cause, or there might have been an insufficient supply of brain material. Normal closure of the skull takes place at from fourteen to fifteen months, and there are cases in which premature ossification occur at the age of six or eight months, and sometimes the baby is so born. The ossification is not always uniform or general. One suture or a part of it only may become ossified. When the ossification is general the whole head is smaller. When partial, as for instance, if it is the sagittal suture which has closed, then the head is low, but broad; if it is the coronal suture which has closed too early, then the occiput is bulging and the forehead is low, as in the negro races, in which the coronal suture normally ossifies first. If this were really premature ossification it must have taken place before birth, as the head is very small, only the size of a six or seven months' fetus. The head feels hard to the touch now, but the anterior fontanelle is not yet entirely closed, so we must exclude general ossification here and fall back on the other and more general class of cases, where there has been an arrest in the development of the brain, from some cause or other. The brain and the bones of the skull are formed at the same time and correspond. In this case it is very probable that something took place to arrest development. When this does happen the arrest of development takes place anteriorly, and the brain then looks like that of one of the higher animals. This non-development may have been caused by an insufficient supply of cell

material, from which to build the brain, or there may have been a meningitis in fetal life. When meningitis does take place in that state, it occurs in the vesicular cavities. The brain is developed from a series of three, afterward five vesicles, usually called the primitive cerebral vesicles, and when inflammation takes place in the vesicular cavities it results in atrophy, so that often there is left nothing but the pia mater, containing only cerebro-spinal fluid. The inflammation may also be external to the vesicle and then compression takes place, at all events, loss of tissue. I have seen a number of such malformations as this take place where a number of pregnancies followed each other in quick succession, not necessarily pregnancies which went to full term, but pregnancies terminating in a miscarriage. In this case, however, we can rule out any such cause as this, for the mother's last child is two and one half years old and she has had no miscarriages. Six weeks ago the child began to smile. Ordinarily a child ought to smile during the third or fourth week. When it does not there is something the matter, either the child is sick or it has a diseased or imperfect brain. Now although smiling is an intellectual faculty, the fact that a child of eight or ten weeks has smiled is not a proof that it has good faculties, for smiling is in the child an imitative act. The prognosis in this case is bad—that is as regards the development of intelligence. Where there is nothing you cannot develop it. It may be possible to aid in the development of whatever brain there is present. The case is a case of microcephalus of the class where brain and bone both failed to be developed, the arrest of development taking place about the sixth or seventh month of fetal life.

CASE III. The mother says that this child, who is seven months old, has been suffering for the last four weeks from catarrh. The baby seems to feel better when the nose discharges. It has a cough at night. The cough does not come on in spells, in that case we should suspect whooping-cough, but it comes on when the child wakes up. Such a cough as that, where there is a nasal catarrh, arises from the irritation created by an accumulation of exsiccated mucus in the pharynx, which, as the child sleeps with its mouth open, dries up in the night-time. The cough is severe but does not mean anything. It is simply pharyngeal. The mother says that the child snores a good deal when asleep. That arises from a sluggish motion of the velum, which is due to the naso-pharyngeal catarrh. The size of the tonsils alone have less to do with it, although they are very red and somewhat swollen. This is simply chronic nasal catarrh, and the cough and the chronic tonsillitis are all dependent on that for a cause. I should propose to treat the case by steam inhalations, and by frequent injections into the nares of a mild saline solution. A kettle of boiling water should be kept constantly in the room where the child is so that it will breathe in the steam continually. The main thing is, however, to keep the nares clean. A mild solution, say a teaspoonful of salt to a pint of tepid water, should be syringed into the nostrils a number of times a day. The nares here are very small because the mucous membrane is swelled, but attention to cleanliness and frequent syringings ought to change the case for the better very soon.

— There is an able and comprehensive article by Dr. E. W. Cushing in the *International Review* for April on the regulation of medical practice.

CANCER OF THE CERVIX UTERI.¹

BY DR. JOHN O. BLAKE.

MALIGNANT disease of the cervix uteri is a malady often coming under the notice of the hospital physician and gynecologist. The distressing nature of the disease, the continuous pain and suffering, the duration, and the inevitable result, all appeal powerfully to our sympathies, and our professional pride is aroused to lessen, if we cannot cure, the distress it occasions. Unfortunately for both physician and patient, it often happens that the disease is not recognized or advice sought until too late. We are all familiar with the errors of patients when undertaking to diagnose their own diseases, but it has been my lot to find more than the usual number of mistakes on this subject. Unfortunately this ignorance is not by any means confined exclusively to the patient, for within a short time I have met in private practice two cases of advanced cancer of the womb in which neither examination nor diagnosis had been made, and in consequence no attempt at treatment. One of these cases died within a few weeks, the disease being already far advanced. Though experience of this kind is unfortunately too common, I must, in justice to the younger members of the profession, say that they would hardly be open to the charge of ignorance or carelessness. Twenty-four years ago the opportunities for gynecological study did not exist in Boston for medical students. I remember the only opportunity I had for viewing the cervix was occasionally when making a visit with Dr. Minot, to whom I am glad to make personal acknowledgment for his interest and kindness to the class in those days. Matters have improved a great deal since, and no excuse of this kind can any longer be alleged by the faithful student as a reason for want of familiarity with uterine lesions. At both of the large hospitals clinical instruction and demonstration are given by the medical staff throughout the year; dispensary clinics also exist, and special instructors teach the subject thoroughly during the last year or years of study. All this awakening of interest has stimulated inquiry, and the result has been a vast advance in knowledge, both of diseases to which this organ is subject and of their successful treatment. As Americans we may feel a pardonable pride that our countrymen are among the foremost of the world in this branch of medicine. Judging by the men at present engaged in this work, and their successful practice, we shall continue in the front rank. All this is simply introductory to the reports of an attempt to relieve certain cases of malignant disease of the neck of the womb, which attempts were based upon reports of similar cases treated successfully, and which in one case were helped by the personal advice and counsel of Dr. Marion Sims, to whom American gynecology is so deeply indebted.

CANCER OF PROLAPSED UTERUS.

CASE I. January 3, 1880. E. B., forty-two, widow, born in Ireland; catamenia first appeared at the age of fourteen, were regular and painless, usually lasting about a week, but occasionally being abbreviated to three days. Was married when twenty-two; has had

no children or miscarriages, but soon after marriage the flow became excessive, lasting two weeks, in the intervals the patient suffered from severe leucorrhœa until twelve or fifteen years ago, when it ceased. Says that coition was never painful, and can give no reason for her sterility. A little while after marriage began to complain of pains in back, side, and lower part of abdomen; pains were not very severe. Says her uterus came down about two years or so after marriage, so that it became visible. She treated it with a T bandage, and was comparatively comfortable until six months ago. A year ago the menstrual discharge began to diminish, and now it is very scanty indeed. Six months ago first had frequent and painful micturition with blood in the urine at times.

Appetite poor, sleeps badly; bowels always costive, being moved only by medicines. Some indigestion; tongue clean and moist. Temperature and pulse normal. No œdema or cough.

On examination find complete prolapse of vagina, terminating in a large conical shaped mass, with base outwards, measuring about five inches in diameter, of ulcerated surface, discharging pus, and bleeding from slight friction. Examination per rectum and suprapubic reveals absence of uterus in normal position. Examination by sound confirms the same.

Upon microscopical examination Dr. E. G. Cutler pronounced it cancer. Following is the result of a similar examination by Dr. R. H. Fitz: "Find your specimen covered with epithelium, resembling that from cervix rather than fundus. The tissues beneath are largely fibrous, with abundant round cells infiltrated. Still deeper are fusiform cells of muscular tissue. The tissues appeared to be continuous from the surface downwards. The examination would suggest prolapse or inversion rather than polypus, although it would be difficult to establish a diagnosis from the microscopical examination without knowing more about the relations of the specimen."

January 13th. Complains somewhat of pain, relieved by morph. sulph., p. r. n. R̄ Vin. pepsin., tr. gentian. comp., āā ʒss. t. i. d.

January 25th. Dr. J. Marion Sims saw the patient in consultation with Drs. Lyman and Blake, and strongly advised removal of diseased mass, including uterus and its appendages.

January 28th. Operation by Dr. Blake. Patient being under ether, a circular incision was made sufficiently high to avoid diseased tissue. After careful dissection vagina was cut through, and the uterus, ovaries, broad ligaments, and Fallopian tubes were carefully isolated from surrounding tissue, special pains being taken to avoid injury to rectum or bladder. Dissection in relation to latter organ was made with special care to avoid injury to urethra, base of bladder, and ureters. After uterus and appendages were well drawn forward, a ligature was passed above fundus, tied very tightly, and parts below, comprising the uterus, ovaries, round ligaments, and Fallopian tubes, were separated and removed. The operation was necessarily somewhat protracted, occupying three quarters of an hour. On account of vascularity of diseased tissue considerable hæmorrhage was unavoidable.

Patient sank a good deal during operation, and rallied but feebly in response to stimulants. Efforts to promote reaction during rest of the day were unsuccessful; patient gradually sank, and died at 9.50 p. m., about twelve hours after the operation.

¹ Read before the Obstetrical Society of Boston, October 9, 1880.

Examination of whole specimen by Dr. E. G. Cutler. Greater portion of tumor was composed of cervix and vagina. The wall was infiltrated with a new growth, cancerous, which extended up into the fundus, evident to senses of both touch and sight. The microscopical examination showed it to be of the epithelial variety, and it did not seem to have invaded glands on the broad ligament. The peritoneal surface was the seat of old inflammation, and there were numerous adhesions, old and new, in Douglas's space, between the uterus and the prolapsed portion of vagina. Left ovary was in a state of cystic degeneration. Left Fallopian tube was occluded, and contained some pus. Right tube and ovary were apparently healthy.

CASE II. March 1. S. M., fifty-five, and married; was well until two or three months ago, though previous to this time had lost some flesh and strength, and had been troubled with vague pains in back, etc., when she was attacked with flowing, coming on gradually at first, but very severe at present.

Was married at eighteen, and has had eleven children at full term, and no miscarriages. About this time first noticed a tumor in the upper part of the vagina, which has rapidly increased in size, and is now the cause of much local trouble and pain. States that any sudden exertion will cause an immediate flowing. Bowels constipated. Micturition difficult. Tongue clean. Anorexia. Pulse and temperature normal.

Examination per vaginam brings finger in contact with a large lobulated mass of diseased tissue, completely encircling and growing from cervix. Anteriorly disease presents a globular appearance, about size of hen's egg. Posteriorly, disease irregular in shape, and filling pretty well upper vagina. Disease is friable to touch, portions of mass disintegrating, and coming away as result of digital examination. Appearances are identical with those found in advanced malignant disease of the cervix.

Operation. In consultation with Dr. Lyman it was decided to remove as much of diseased tissue as possible. Patient declined being etherized. Uterus having been drawn well down it was found that the *dérasseur* would most effectually remove the disease. Wire was passed around mass, and tension applied when the wire broke. Chain was then substituted, and diseased portion, including a small section from cervix, removed without injury either to urethra or bladder. A small mass remaining on posterior wall was thoroughly removed with Lieman's scoop, and entire stump freely touched with strong nitric acid, afterwards an alkaline solution was applied, followed by a glycerine tampon. Morph. sulph., one sixth grain, subcutaneously.

March 3d. Second dressing made. Nitric acid applied, followed by glycerine tampon and dry cotton. Hot vaginal douche every morning. Dr. Cutler examined a specimen of the tissue, and pronounced it cancer.

March 9th. Incised surface covered with healthy granulations. R̄ Ferrated tr. cinchona, ʒi. t. i. d. R̄ Fowler's solution, gtt. v., t. i. d.

March 27th. Patient has had applications of nitric acid once in five days, followed by glycerine dressing. Granulating surface now contracted to size of a quarter dollar, of healthy appearance, and without discharge. General condition good.

April 2d. A growth of exuberant granulations on anterior lip (cancer?) was scooped off, and nitric acid applied, followed by glycerine tampon. General condition improving.

April 9th. Disease involves whole posterior lip, having extended with marked rapidity; cancerous nodules over incised surface of anterior lip.

April 12th. Diseased mass on posterior lip was removed with knife, when an opening was made into the peritoneum, admitting tip of finger. One silver suture inserted. Morph. sulph., p. r. n.

April 14th. Complaints of occasional darting pains in abdomen.

April 15th. No febrile disturbance.

April 23d. Diseased surface looks well, and shows only a small granulating part. Suture removed, and parts united. Patient was discharged relieved; to be examined once a month.

August 23d. After leaving hospital patient was very well for two months, when the pain returned; she kept about her work until three weeks ago, when the flowing again began. General health in the mean time has been good. Examination per vaginam shows a mass of granulations growing from posterior lip, extending up cervical canal, and beginning to invade upper vaginal wall. Mass thoroughly removed with curette, scoop, and scissors, and saturated solution of chromic acid applied. R̄ Morph. sulph., p. r. n.

August 24th. Parts looking very well. Chromic acid again applied.

August 26th. Glycerine tampon applied to cervix twice a day. R̄ Ferri et quiniæ cit., gr. v., vin. Xerici, ʒss. t. i. d.

September 6th. Slough almost entirely thrown off. Parts look much more healthy.

September 11th. Discharged, relieved.

CASE III. March 10th. C. D., forty and widow. Has had four children, the last one thirteen years ago. No miscarriages. Catamenia regular until last Christmas, when she first noticed a discharge from the vagina, with a very offensive odor, which was followed by flowing two days after, this being her regular time to be "unwell." This sort of thing continued, the flowing being much increased by any heavy work, together with pains in back, especially on left side, anorexia, constipation, etc. Micturition normal. Tongue furred. Temperature 100° F. Pulse 115.

March 18th. Examination per vaginam showed whole of both posterior and anterior lips, as well as cervix to within a quarter inch of vaginal junction, one mass of ulcerating growth, which bled freely when manipulated, the presenting surface being two inches in diameter. Vagina tamponed with Monsel's solution on cotton. R̄ Ferri et quiniæ cit., gr. v., vin. Xerici, ʒss. t. i. d.

March 19th. Patient etherized. Examination showed the whole cervix to consist of one mass of epithelioma, extending under mucous membrane beyond vaginal junction. Diseased part removed up to vaginal junction by means of curette, and as far as internal os. Hemorrhage not excessive. Nitric acid applied, and cervix tamponed with cotton soaked in Monsel's solution.

March 20th. Hot carbolized vaginal douches twice a day.

March 30th. Once in three days surface has been dressed with a nitric acid and glycerine tampon. Parts have contracted one half, but whole surface shows a sloughing condition, with here and there a prominent cancerous nodule. Free discharge of pus noticed at the time of each dressing.

April 5th. Posterior vaginal wall at junction of cer-

vix consists entirely of cancerous mass easily breaking down; same condition anteriorly. Mass removed by curette and scissors, even on to vaginal wall. Nitric acid applied, followed by dressing of Monsel's solution.

April 9th. Dressing removed, and several small cancerous nodules on posterior and one on anterior wall removed. Nitric acid applied, followed by glycerine tampon.

May 11th. Growth extending very rapidly, occupying surfaces previously denuded by operations, also involving body of uterus through the inner os and both walls of the vagina, so that any attempt to remove the growth would open into the peritoneal cavity.

General condition greatly improved. Discharged, relieved, at own request.

CASE IV. December 12, 1878. A. N., widow, aged thirty-seven, enjoyed good health till two years ago, when catamenia became irregular. Has had three children at full term, the youngest being nine years old. For the past two weeks has been flowing steadily; no offensive discharge from vagina. Appetite poor; bowels constipated. Pulse and temperature normal.

December 13th. Examination per vaginam shows the whole cavity of the cervix to be ulcerated and eroded, admitting tip of finger as far as internal os. Vaginal aspect healthy. Thin sanguineous pus exuding from cervix. Plug of cotton soaked in glacial acetic acid inserted into cervix, and glycerine tampon applied.

December 16th. Cervix secretes pus, comparatively healthy in appearance. Parts washed with carbolic solution, and ulcerations touched with glacial acetic acid: plug of lint soaked in the acid inserted into cervix.

December 20th. Carbolyzed injections, with slippery-elm tea, night and morning.

December 22d. Cervix touched with glacial acetic acid. No pain; general condition good.

January 1st. R̄ Ferri et quiniæ cit. gr. v. t. i. d. Friedrichshall before breakfast.

January 7th. Glycerine tampons inserted twice per day. Os looking well. Lunar caustic applied, followed by glycerine tampon. Suppository of morphia and belladonna at night.

January 29th. Patient has been made comfortable with morphia. General condition good. Examination per vaginam shows complete cicatrization of cervical tissue. Uterus moderately retroflexed and movable. Cicatricial tissue indurated, due to operations. A seropurulent leucorrhœa, probably of vaginal origin.

January 31st. Discharged, relieved.

CASE V. Mary P., married, aged forty-three, entered the hospital January 27th, with the following history: Has had ten children; labors normal; oldest child twenty-two, youngest three years of age. Menstruates regularly every four weeks: flows but three days; uses but two or three napkins each day. Has had more or less uterine trouble for the past year. For the past three months has had severe pain in the back and in the lower part of abdomen. An abundant watery, offensive discharge from the vagina. For the past week has noticed a swelling in the lower part of abdomen on the right side. Difficult micturition for past two months. Bowels constipated. Appetite good. An examination showed cervix much destroyed from some previous caustic application. Os open, ad-

mitting the finger freely to interior of uterine cavity. Interior of uterus found to consist of softened, somewhat pulpy, nodulated tissue, which bleeds freely, and is evidently of a malignant character. Much pale, flabby, exuberant granulations around what remains of the cervix. Uterus not much enlarged. External examination discovers a mass somewhat indistinct in right ovarian region. A portion was removed from inside uterus and sent to Dr. Cutler, who pronounced it to be epithelioma. Patient was ordered citr. quinine and iron, gr. v. t. i. d. Fowler's sol., five minims after each meal. Hot carbolyzed douches twice a day.

February 3d. Interior of uterus thoroughly curetted and all fungoid tissue removed, after which a strong solution of chromic acid was applied to curetted surface. Retention of urine followed the operation, but lasted only two days. Ordered opium p. r. n.

February 10th. Pain in back quite severe. Discharge from vagina much less offensive. Douches come away quite clear.

From February 15th there was continued improvement in both general and local condition. Expressed herself as feeling well, except that she has a pain in small of back.

March 2d. On examination no apparent evidence of disease was found.

March 5th. Discharged, relieved.

REMARKS.

These cases fairly represent disease of this organ as it usually comes under the physician's care, and the question to decide is whether surgical interference is justified by the results. While at first but little can be said in favor of operation from the account of these results, yet we must remember that temporary relief from pain and the prolongation of life for months, if not years, are considerations which control our decisions in other cases and which are entitled to great weight here. The unfortunate termination of the first case was, in a great degree, anticipated; yet I cannot but feel that the operation was called for. I may say that whatever doubt lingered in my mind was removed by Dr. Sims, who kindly saw the patient, and strongly advised extirpation as performed. Operations of such severity are naturally attended by great shock to the nervous system as well as much loss of blood, a condition dependent on the nature of the disease and length of time required. Besides, the rarity of operations of this character leaves a want of skill which is not easily remedied. I suppose I only voice the sentiment of every gentleman present in saying that in future operations many points will be treated differently, and the chances of cure increased by experience gained in each new case. The records of ovariectomy give abundant proof of this.

In relation to Case II. the result has been very different. This patient continues quite well in general health, able to attend to her household duties, free from pain and hæmorrhage, and suffering only from a leucorrhœal discharge, which disinfecant injections render inoffensive. There is as yet no cancerous cachexia or vesical irritation, and from present appearances her prospect of life appears good for many months at least. This result has been obtained only by constant supervision and removal of the disease on its reappearance. As often as once a month either the curette has scraped away exuberant granular adhesions, or applications of nitric or chromic acid have kept the disease in subjection.

As yet there is no evidence of the fundus uteri becoming invaded, though it is only a matter of time when both that and the pelvic viscera will become involved.

Case III., operated upon by Dr. Doe and kindly permitted by him to become one of this group, has, I understand, not done as well, from the fact that circumstances did not allow him to follow up the treatment so persistently. He will give us full details of the subsequent history.

Case IV. was primarily under the care of the late Dr. George H. Gay, and afterwards of our president, Dr. Lyman, who had the opportunity of treating it in its active stage. From him it descended to me as his successor in service at the hospital. At that time very little in the shape of active treatment remained to be attended to, and it is briefly alluded to here so that he may give us an accurate account of the earlier stages of the disease and treatment, while I can testify to the cure and entire absence of disease up to the present time. I recently carefully examined the patient at my office, in order to be able to report her condition one year after leaving the hospital.

Two of these cases strikingly resemble a group treated somewhat similarly by Dr. Marion Sims, and reported and commented on by him in the *American Journal of Obstetrics*. As the subject is doubtless familiar to members of this Society I have refrained from making reflections or suggestions, preferring to offer the paper as a text upon which members can express their opinions fully. I am for myself decidedly in favor of surgical interference and complete removal of the disease at the earliest possible opportunity.

I am equally decided in my opinion that the disease is primarily local in origin, often starts from a lacerated cervix, or long-continued abrasion, erosion, or so-called ulceration of the os, and that if we could prevent solution of continuity of the cervix uteri, or cure them before they become chronic, we should have fewer cases of malignant disease of that organ to treat.

PERFORATING ULCER OF THE DUODENUM.¹

BY A. F. CLARKE, M. D. HARV.

J. S. SYMONS, physician to the Bristol General Hospital, writing, upwards of forty years ago, on duodenitis, remarks that "the elevated patches which occur, both in the acute and chronic forms, are caused by turgescence or hypertrophy of the *glandule conglomerae Brunneri*, which abound in this division of the intestine." He doubted whether acute inflammation is ever confined to the duodenum. "Sometimes the bile duct is obstructed by the swollen state of the membrane, or by the accumulation of viscid mucus." He further observes that "the sympathetic derangements in duodenal are scarcely less extensive than in gastric disease." The more special exciting causes are substances passing undigested from the stomach and irritating, or even accumulating in, the duodenum, such as fruits, crude vegetables, the harder animal substances, particularly salted meats, the teguments of fish," etc. He recognized ulceration as a structural disease of the duodenum, but regarded the discrimination from similar diseases "all but impracticable."

Andral, in his Medical Clinic, Diseases of the Abdomen, says, while speaking of lesions of the digestive tube, that he had very seldom found the duodenum affected. Wood, in his Practice of Medicine, speaking of the diagnosis of duodenitis, says that perforation of the bowel (duodenum) sometimes takes place from simple ulcer, as in the stomach from gastric ulcer, with fatal effects. A duodenal ulcer may be suspected when, along with pain, at a fixed point in its structure, occurring two or three hours after a meal, with tenderness in the same spot on pressure, there are occasionally black stools from admixture of blood, without vomiting of blood. The bowels in duodenitis are generally slow, but readily acted on by cathartics. Nearly all authorities speak of the erosion or ulceration of the large blood-vessels which supply the duodenum and the consequent excessive hæmatemesis as a complication of frequent occurrence.

Jones and Sieveking, in their Manual of Pathological Anatomy, after having quoted Rokitsansky on the Seat of Ulcer in Abnormal Conditions of the Stomach, observe that "a similar ulcer may form in the upper oblique portion of the duodenum, but not as far as observation has yet shown in any other part of the intestinal canal;" that the ulcers near the pylorus are circular, from three to six lines in diameter, "with a sharp peritoneal edge as if a round piece of the parietes had been punched out." Formerly much was said in regard to the chemical action of the healthy gastric juice on the tissues after death, which action had been ascribed to disease. Watson, in his lectures on the Principles and Practice of Physic, refers to the whole subject, and makes some very pertinent remarks in relation to it. "Now and then the gastric juice passes out of the stomach into the œsophagus or into the duodenum, and these parts exhibit traces of its action." "These apertures (perforations) produced by the gastric juice have soft and ragged edges, and are irregular in their size and outline." Laube, in Ziemssen's Cyclopædia of the Practice of Medicine, says, "the prototype of the peptic ulcers is the perforating ulcer of the duodenum; the primary lesion is a local arrest of the circulation, and that the formation of the ulcer at this point is a secondary and necessary result of the action of the digestive juice has been made probable by the experiments of Panum, and has been directly demonstrated by Merkel's case, which showed at the autopsy an embolized artery in the base of a duodenal ulcer. That the ulcer has a sloping shape, and the loss in the serosa is less than in the muscularis, while the greater loss is in the mucosa; the edges are sharply cut, not thickened, and in the older ulcers are indurated." According to the same authority Krauss's compilation of forty-seven cases showed that the ulcer, in the great majority of cases, is in the upper portion of the duodenum, and that there is usually only one. Duodenal ulcer is a comparatively rare disease, being in the proportion of hardly one to thirty of those occurring in the stomach. Duodenal ulcer first manifests itself by the symptoms which immediately usher in the fatal result, or the rapidly fatal perforation takes place in the midst of apparent health; usually, however, even when the duodenal disease runs a rapid course, careful inquiry as to the general health of the patient will show that he had previously suffered from slight dyspeptic symptoms, oppression in the epigastric region, and uncomfortable feelings after meals. The diagnosis is always doubtful, and a distinction from gas-

¹ Read before the Cambridge Society for Medical Improvement, January 24, 1881.

tric ulcer is well nigh impossible. The lesion is more frequently met with at autopsies of persons between thirty and forty years of age. Da Costa, in his *Medical Diagnosis*, second edition, remarks as follows: "there is a disorder with almost identical symptoms as gastric ulceration; namely, the corrosive ulcer of the duodenum." Further, he says, "were this affection more frequent it would be a constant source of error in diagnosis." That both in the acute and chronic cases the diagnosis is, with our present means of research, impossible. Niemeyer says "this affection is not a proper ulceration, but a necrosis and a solution of the necrosed part of the intestine by gastric juice. In one thousand post-mortem examinations made at the Prague Institute for Pathological Anatomy Wilk found perforating duodenal ulcer only twice, while in seventy-four cases he found either ulcers or their cicatrices." From the analysis of the cases known it did not appear whether certain causes, such as burns of the skin, induce this disease. "Perforating ulcer of the duodenum appears to remain latent until the fatal termination more frequently than similar ulcer of the stomach. That peritonitis from duodenal runs its course more rapidly than from gastric ulcer, probably from the admixture of the bile which escapes into the abdomen." Further, he mentions that a number of cases are reported where duodenal ulcers run their course with periodical attacks of pain. That when the pain occurs several hours after meals, in connection with other symptoms, the diagnosis will be made out with great probability. Flint says that perforation is not a constant effect of an extensive burn; but a sloughing ulcer is apt to occur at the upper part of the duodenum, within a few days after an extended burn. In the *Boston Medical and Surgical Journal*, volume xc., there is mentioned a case of duodenal ulcer "occurring in a child who had been burned over the chest and abdomen." This case was taken from the *British Medical Journal*. It is so briefly reported that it is impossible to arrive at a correct conclusion as to the real cause of the ulcer. "The duodenum was perforated and glued to the surrounding surface by lymph." According to Condie, and many other able observers even before his day, acute gastritis had been recognized as a disease of frequent occurrence during infancy and childhood. Condie says, "it is seldom that the stomach is alone affected; in the great majority of instances the inflammation extends to the duodenum and other small intestines." Further, he says that the disease may so terminate as to cause perforation.

Occasionally, instead of perforations into the peritoneal cavity, adhesion (as has already been mentioned) to the pancreas, liver, or gall-bladder occurs, external perforation has happened, or an extensive sloughing along the dorsal region has occurred, and an abnormal communication with another viscus or organ has been established. Dalton, in his *Physiology*, says: "In the human subject it is rare to make an examination of the body twenty-four or even thirty-six hours after death without finding more or less softening and disintegration of the tissues from the gastric juice. In some instances all the coats of the organ are found destroyed, and a perforation is produced leading into the peritoneal cavity." "But during life the chemical changes of nutrition which are going on in the tissues guard them from this influence and effectually preserve their integrity." The chemical changes here referred to by Dalton evi-

dently mean a normal and healthy activity of the circulation in the parts, and (according to others) the alkalinity of the blood and the alkalinity of the intestinal and pyloric secretion and the reabsorption of the redundant digestive acids after chymification and chylification have taken place. According to Garland,¹ not only the secretion of the intestine but that of the pylorus is alkaline.

Having reviewed the authorities on the subject thus much, I will offer the following case of perforation of the duodenum into the abdominal cavity occurring in my practice.

H. B., aged thirty-two years, colored, a hostler, was taken suddenly ill, while he was going to his work at a stable on the morning of August 1, 1880, with intense pain in the abdomen, particularly in the epigastrium, and on the right side extending downwards. He had not been very well for two or three days before, having suffered with some pain in those regions; his sleep was disturbed by the pain the night before, but he had continued his services as usual at the stable, and had taken some breakfast that morning. Dr. Holt was immediately called; this was about ten A. M. The patient was found standing, but bending forwards, and complaining of severe pain resembling colic. A subcutaneous injection of morphia was administered, and the patient was removed to his boarding-place, and soon became easier. There was at that time no chill nor vomiting, but great tension or hardness over the abdomen. I was called at five A. M. August 2d, and took charge of the case. At that time I found the patient had suffered intensely during the night from the pain in the abdomen, especially in the epigastrium, accompanied at times with more or less tenesmus. Pulse 120 and moderately full; temperature 102° F. There had been some nausea, but no vomiting. Micturition normal, but he had had no passage since his attack began. The abdomen was exceedingly tense and hard, but there was not much flatus. Copious injections of warm water, with soap and oil, were given, but not the slightest sign of fecal or other matter was voided. Full doses of morphia and small doses of saline laxatives were employed. Also counter-irritants, including emplastrum cantharidis, were freely used. I saw the patient three times the first day, but no material changes in symptoms was developed. August 3d, eight A. M. Pulse 120, weak and compressible; temperature 103° F.; there was now vomiting, but without stercoraceous matter or blood. Tympanites had increased. Still no motion of the bowels had occurred, though enemata were repeated. Dr. Norris now saw the case with me. Enemata again resorted to, and the sphincter ani was ruptured with the view of exploring more thoroughly the parts by the insertion of the hand high up above the rectal pouch. The patient's condition, however, was so feeble that further examination was abandoned. The patient died at two P. M. August 3d, this being fifty-three hours from the commencement of the attack.

Autopsy, four P. M., August 4th, Drs. Holt and Clarke present. About three centimeters from the pylorus, on the upper portion of the duodenum, there was found a round ulcer which had perforated into the peritoneal cavity; the aperture appeared as though it had been cut out with a punch. There was no indication of any inflammation about the ulcer, the edges were smooth and not raised above the surface of the parts, and only

¹ Boston Medical and Surgical Journal, vol. ciii., No 19.

a little red around their inner margin. The stomach was healthy and contained a considerable quantity of fluid which had been swallowed by the patient. The peritoneum was red and injected and presented the first stage of inflammation. Very little fecal matter was found in the intestines, but a large quantity of fluid had already escaped into the peritoneal cavity; and on lifting the duodenum, which was greatly distended, more was seen to ooze or gush through the opening which the ulcer had made. No tuberculosis nor other lesion was observed.

In recounting the history and symptoms of this case, several important features present themselves for our consideration. First the occurrence of the lesion is comparatively rare according to nearly all authorities on the subject. In the next place is to be noticed the great difficulty or impracticability of forming a correct diagnosis during life, according to our present means of research. The first symptoms simulated ordinary cold, as there was no chill nor other constitutional disturbance in the beginning, but the great hardness and rigidity of the abdomen, and the character of the pain, which was not paroxysmal, excluded this view. Was it imagination? Repeated enemata produced no defecation; the rectum was free from any obstruction; no tumor was felt by external manipulation; the pain and disturbance were seated higher up than is usual with intussusception; moreover, this latter disease occurs more frequently, in infancy and childhood. Was it typhlitis? The original seat of the pain excluded this view. Was it peritonitis? Peritonitis for the most part is a symptomatic disease: the history, temperature and other constitutional symptoms did not indicate this. Was there gastritis? At first the stomach was able to bear whatever was prescribed, and there had been no history of such a disease. Was it enteritis? Certainly not of the mucous coat, as the disease was not attended with diarrhoea nor dysentery, though there was some tenesmus at times. There was no history nor symptoms of a previous constipation. After the autopsy had removed the uncertainty the significant words of the author already cited (Da Costa) were realized, "were this affection more frequent it would be a constant source of error in diagnosis." The treatment usually adopted by most authorities in such cases is merely palliative. But does not the science of medicine, with its recent advances, offer any aid to the diagnosis and treatment of such cases? We know that the antiseptic treatment in surgery, and more especially in abdominal surgery, has achieved many brilliant results.

A careful observer recently remarked that formerly nearly all cases of ovariectomy, even when attended by the most experienced and accomplished surgeons proved fatal, while now with the antiseptic treatment recovery in ovariectomy is the rule and death only occurs in exceptional cases, as shown in the series of cases lately reported by Dr. John Homans.¹ But this is only one item of what may be mentioned. According to T. H. Buckler,² writing from Paris (June 15, 1880), "there is no such thing as an idiopathic peritonitis; the peritoneum is less liable to become inflamed than any other tissue or structure of the body, and when inflammation does occur in this membrane it is invariably symptomatic and dependent without exception on some foreign body, mischief or pre-existing cause introduced or

applied." Several cases and autopsies are given in his paper in illustration of this statement, and some cases where the abdomen was reopened at the autopsy to establish the certainty of the symptomatic nature of the peritonitis. Dr. Buckler suggests that the cavity of the abdomen may be opened by lineal incision at almost any time required, not only for the performance of operations but for purposes of diagnosis. Thus, he says, a new field is open to both the physician and surgeon as it has been to the ovariectomist. We would incidentally remark that Dr. Buckler's paper on the inaptness of the peritoneum to inflame we cannot recommend too highly for the careful considerations and timely suggestions it offers to the profession on matters allied to that we have been treating.

RECENT PROGRESS IN OPHTHALMOLOGY.

BY O. F. WADSWORTH, M. D.

OPTICO-CILIARY NEUROTOMY.

THE operation of division of the optic and ciliary nerves as a substitute for enucleation has, since its introduction in 1879, by Schoeler, met with varying amount of approval or disapproval from different operators. Some have abandoned it on account of unsuccessful result in their first cases, others have given modified approval while restricting within narrower or wider limits the conditions under which it is to be regarded as indicated or justifiable, by others, again, it has been received and practiced with marked favor. Regeneration of the divided ciliary nerves, the danger of which has been from the beginning the strongest argument against the operation, has been in a number of cases assumed on more or less satisfactory evidence. Symptoms threatening sympathetic inflammation have induced enucleation after neurotomy has been done, and recurrence of pain has also led to enucleation in a not inconsiderable number of cases. The occurrence of hemorrhage during or shortly following the operation has in some cases been sufficient to induce immediate or subsequent enucleation or to complicate the course of healing, and is the danger which has perhaps been most frequently feared and the objection most generally urged. It is hardly to be doubted that differences in the manner of executing the details of the operation, and they have been not few nor unimportant, may be responsible for some of the imperfect results obtained, and more extended experience may very likely demonstrate the necessity of a certain selection of cases.

Schweigger, who at first contented himself with dividing the opticus, rolling the globe forward and carefully clearing its posterior surface, has since modified his method. He has now³ in a large series of cases divided the opticus ten mm. behind the sclera, then, rolling the eye by means of a sharp hook, divided the insertion of both oblique muscles, cut off the opticus close to the sclerotic and cleared the surface of the eye up to the equator, including the venae vorticosae also in the dissection. As before, he commences the operation by inserting catgut sutures in the internal rectus and then dividing it, reuniting the muscle to its tendon when the proceeding has been completed. He admits that without resection of a long piece of the opticus regeneration of the ciliary nerves may possibly occur,

¹ Boston Medical and Surgical Journal, vol. cii., p. 50.

² Boston Medical and Surgical Journal, October 28, 1880.

³ Handbuch der Augenheilkunde, 4te Ausgabe, 1880.

with such resection he believes neurotomy interrupts the communication between the two eyes with as much certainty as does enucleation.

Pflüger,¹ also, in his later cases has resected six to ten mm. of the opticus and since this modification has seen no return of pain or of sensibility of the cornea.

Boucheron, Knapp, Meyer, and others have resected more or less of the opticus. Meyer² divides both the internal and external rectus muscles, both obliqui, and resects the nerves, and in two years during which he has employed this method, in twelve cases from six to forty-six years of age, has seen no relapse. Schoeler has suggested that the danger of reunion of nerves might be obviated if thought necessary by the production of a strong deviation of the eye by sutures,³ or the advancement of a muscle⁴ as the closing step of the operation.

Widely different is the operation proposed by Smith.⁵ He divided the nerves by passing his scissors through a small opening in the conjunctiva between the internal and inferior recti, and again from above between external and superior recti. Such an operation, done in the dark, can hardly furnish proper guarantee of division of all the nerves. In the case he reports, sensibility of the cornea and sympathetic disturbance of the other eye returned. Still, more radical methods have not always given exemption from like result.

The return of sensibility in the cornea has been generally regarded of ominous significance as demonstrating reunion of the ciliary nerves. That sensibility persisted after operation in vascularized parts of the cornea was pointed out by Schoeler in the report of his first series of cases, and has been abundantly verified since. It is sensitiveness of the transparent cornea that is dreaded, and if the deduction is justified that this is reliable evidence of nerve regeneration, then regeneration has been shown in quite a number of cases. Experiments on dogs by Redard⁶ showed beginning return of sensibility in the cornea in three to four months and complete restoration in one and one half years. Dor⁷ one and one half years after operation found the cornea sensitive and that the iris reacted in consonance with that of the other eye under the stimulus of light. In a case reported by Schoeler,⁸ nine months after neurotomy the iris reacted to atropine and eserine, although the globe was not sensitive to pressure and the cornea remained completely anæsthetic.

But the cornea is supplied in part with nerves from the conjunctiva, and more than one writer has referred a sensibility limited to the peripheral parts of that membrane to the influence of these nerves; yet no one, apparently, has suggested that such an extension of the conjunctival nerve branches might occur as to render the whole corneal surface sensitive.

Recurrence of pain in the eye, of which also a number of instances have been related, is considered further evidence of reunion.

The anatomical evidence of regeneration is still but meagre. From the report of an experiment by Boucheron on the dog, given by Redard,⁹ the inference is

⁹ De la Section des nerfs ciliaires et du nerf optique. Paris, 1879.

that the ciliary nerves within the eye were found regenerated. Yet Poncet at the International Congress at Milan,¹⁰ while referring to this very case and to subsequent experiments by Redard, and stating that he had demonstrated all the stages of regeneration, so that "in the dog the regeneration of the nerves is without question histologically perfect," adds, "this regeneration has, however, only been shown in the extraocular parts, [central ends?] of the ciliary nerves, it is still to be sought in the ciliary plexus and in their subchoroidal course." As Poncet himself prepared the "report" it must be accepted as accurate on this point. Moreover, that Poncet does not believe the risk of regeneration, in man at least, to be great, would appear from a paper¹¹ in which he lays much stress on the changes in choroid, retina, and vitreous excited by the operation, and proposes a method for its performance intended to reduce the amount of these changes, according to which the nerves are divided some six mm. behind the eye, but without resection, without division of any muscles, and without rolling the eye to make sure by ocular inspection that no nerves have escaped section.

Bunge¹² gives two cases from Graefe's clinic, in one of which complete sensibility of the cornea was found seven months after neurotomy, in the other neurotomy was done three times and finally enucleation for pain "in the orbit" and "behind the eye," the cornea being without sensation, but the ciliary body somewhat tender to pressure. In the former of these eyes Kuhn found one ciliary nerve in a condition indicating active regeneration, in the latter were two nerves presenting similar appearances. All other ciliary nerves in both eyes were completely degenerated. Kuhn preferred to believe that in these cases the regenerating nerves had never been divided, but only injured by stretching and contusion, a conclusion which Bunge is not disposed to share.

Finally Hirschberg¹³ reports a case of enucleation for pain and sensitiveness, after two neurotomies, from the outer and the inner side, had been done by an experienced oculist, the eye containing a long piece of iron. He states briefly "the ciliary nerves were carefully dissected out on the inner surface of the sclera, and found histologically normal." The full force of this statement can scarcely be intended, for then it would appear that in the space of eleven months, which had elapsed since the last neurotomy, all the ciliary nerves had reunited and undergone complete regeneration, almost an incredible result.

Many have reported cases of troublesome hæmorrhage, and Warlomont¹⁴ has devised *ciseaux hémostatiques*, a combination of scissors and compression forceps, to obviate the danger of this complication. In individuals with atheromatous arteries hæmorrhage may perhaps often necessitate enucleation; in others, those most familiar with the operation by personal experience do not seem to have met with special inconvenience in this respect. The method of operation may well have been at fault in some instances, and it is to be remembered that neurotomy, if successful, is only a substitute for enucleation.

So far as the reporter is aware no case of sympathetic inflammation after neurotomy has yet been published,

¹⁰ Compt-rendu du Congrès, etc., l. c.

¹⁴ Annales d'Oculistique, T. 84, p. 82. 1880.

although eyes have been removed because such inflammation threatened. Knapp¹ states he "learned" that in a case of Dr. Williams' neurotomy had to be followed by enucleation on account of sympathetic ophthalmia. This is a mistake. Hirschberg, however, in a note appended to the statement in the *Centralblatt* says, "an eminent young colleague from Germany informed me recently that he was in possession of two eyes which had been enucleated because, spite of optico-ciliary neurotomy, sympathetic inflammation had set in. Farther particulars will be published." No farther reference to the cases appears in the *Centralblatt* up to February, 1881.

The opinions expressed as to the merits of the operation have been many and various. Schoeler, as perhaps might be expected, is a warm advocate in its favor. Schweigger² asserts that if resection of the opticus be made as he describes, "the domain of the latter (enucleation) would therefore be restricted to intra ocular tumors, and eventually to eyes in which foreign bodies maintain a chronic inflammation. It is to be wholly rejected for cases in which pain in blind eyes is the reason for the operation."

Pflüger³ would prefer enucleation in persons who could not be depended on to observe proper watchfulness themselves, or could not for a long time be under the observation of the physician.

Meyer⁴ would reserve neurotomy for cases of neuritis alone; for severe cases of sympathetic ophthalmia would choose enucleation.

Knapp⁵ gives no decided opinion for or against. Hirschberg⁶ has from the first opposed the operation, which he has yet performed nine times without disagreeable accidents, but in all cases which he has had the opportunity to watch for a year sensibility of the cornea returned whenever it had been present before the operation. He believes "that we shall soon abandon our overestimation of the value of optico-ciliary neurotomy."

QUININE AMAUROSIS.

Most of the modern text-books on ophthalmology contain some reference to quinine amaurosis. The reported cases are, however, very few. Gruening⁷ could collect but eleven. He reports the case of a lady, aged thirty-five, in whom, about the sixth week of pregnancy, a slight hemorrhage followed by a fetid discharge necessitated the removal of the contents of the uterus. The operation was attended with but slight hemorrhage; a rise of temperature to 106° F. followed. In thirty hours eighty grains of sulphate of quinine, in ten-grain doses, was administered. Shortly after the last dose there was a convulsive attack, with twitching of facial muscles and jerking of limbs, but not complete loss of consciousness. When the attack had passed she was totally deaf and blind. Twenty-four hours later hearing was partially recovered, but blindness still complete. The pupils, widely dilated, did not respond to light, but contracted somewhat with strong convergence of the eyes. The media were clear; the optic discs very pale, but transparent and well defined; the retinal vessels, both arteries and

veins, so excessively attenuated as to be scarcely visible in the inverted image, while the slightest pressure on the eye caused them to become absolutely bloodless. At the macula was a cherry-colored spot surrounded by a zone of bluish-gray opacity. The patient was very pale, rational, complained of no pain, but of noise in her head. No albumen in the urine.

Generous diet, recumbent position with the head low, instillations of eserine, inhalation of nitrite of amyl, administration of digitalis. Eight days after the attack the cherry spot at the macula and the surrounding opacity had disappeared, but there was no other change. A fortnight later there was quantitative perception of light, which was lost for a time after the patient had sat up for three hours, and again lost during menstruation. Then sight gradually improved till at the end of three months central vision was $\frac{2}{3}$, but the field much contracted, and no color perception. The pupils, moderately dilated, contracted on accommodation, but not to light. The discs were very pale, transparent; the retinal vessels filiform. Six months from the attack the color sense had returned, but was still imperfect; the field was still contracted, though larger; no change in the eyes, except slight reaction of moderately dilated pupils.

A discussion of the various affections which may produce sudden and total blindness shows that all differ from quinine amaurosis in their onset, course, termination, and ophthalmoscopic appearances. Gruening concludes that the unequivocal cases of quinine poisoning, with amaurosis, offer a remarkable congruence in their essential features. "The patient, after the ingestion of a single dose or of repeated doses of quinine in varying quantities, suddenly becomes totally blind and deaf. While the deafness disappears within twenty-four hours, the blindness remains permanent as regards peripheric vision, central vision gradually returning to the normal after some days, weeks, or months. The ophthalmoscope reveals an ischæmia of the retinal arteries and veins, without any inflammatory changes. In view of the constancy of these symptoms and the uniformity of the ophthalmoscopic picture, we are entitled to demand for this distinct type of amaurosis a recognized position in the pathology of the optic nerve and the retina."

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, SECRETARY.

MARCH 12, 1881, seventy-three members present. DR. R. M. HODGES in the chair.

DR. F. A. HARRIS read a paper entitled, A Case of Abortion with Acquitall. The following is an abstract: "This case is presented to the society not because of anything remarkable in the circumstances, but because it so well illustrates the difficulties lying between the detection and punishment of a crime. It shows especially the quality of the professional so called expert testimony offered in such cases, and the necessity for a speedy and radical change in the laws governing such testimony if we wish to preserve the good name of the profession. I was summoned one evening to investigate the circumstances attending the death of Mattie S., aged twenty-two, single. The account of

⁷ Archives of Ophthalmology, x, 1.

the officer showed that death had ensued after an illness of some weeks.

There was nothing unusual in the position or surroundings of the body, except numerous blood stains on the wall next to which the bed had stood. A superficial examination of the body showed emaciation, tympanites, enlarged breasts with dark areolæ around the nipples, a dark line extending from the navel to the pubes, one half centimeter in width, foul-smelling purulent matter issuing from the vagina, and swelling of the external genitals. It was ascertained that Mattie had come there to board some time previously; that a young man had paid her bills, and it was understood that they were to be married in the spring. She had been pretty well when she first came, but about a month previously began to suffer severely from cramps in the abdomen. About three weeks before her death she was obliged to take to the bed. The cramps continuing and growing more severe, one week later the young man, who had been taking care of her, called in a so-called doctor, who came immediately, bringing a bag of instruments. On entering the room, without asking any questions, he etherized the woman, pulled three teeth, and did some operation on her womb. He told the mother and sister of the young woman, and also the landlady, that he had found the blood congealed in the womb, and that he had had to start it or she would have been dead in three hours. After the operation a pot full of blood, with something round and white hanging over the side, was carried from the room. The sheets and mattresses were soaked with blood. No child was seen unless by the doctor and young man. After the operation he called to see the girl several times, and then went into the country. The girl got no relief from the pain, and a regular physician was called, who gave it as his opinion that the girl was suffering from peritonitis following an abortion. A homœopathic practitioner, afterwards called, gave the same opinion. The girl confessed to her sister that she had been in the family way, and was about six months along. Mattie had grown steadily worse after the operation, had had chills, high pulse, diarrhœa, abdominal pain, and swelling; as the so-called doctor expressed it, she was bloated from her neck to her knees. Foreseeing what might be one line of defense (events proved my surmise correct) I particularly questioned the landlady as to the character of the cramps that Mattie had had; she declared that they were like colic; that the girl had never had a fit. On the morning the doctor was there she had seen Mattie, and she thought that she was suffering from cramps, she was sure she did not then have anything like a fit. This evidence was sufficient to point strongly to the fact that an abortion had been committed, but recognizing the fact that such an operation may be legitimate under certain circumstances, I proceeded to get the young man's and the doctor's version. I was shown first a pocket-book the doctor had attempted to throw away after his arrest, and a bag of instruments taken from his house. These latter were such as any physician would naturally have in his house. In the pocket-book I found a note made by the young man in favor of the doctor for the sum of fifty dollars. The young man said that he had not seen the doctor for some time; he then attended him personally; he expected to pay the doctor for his services, but had given him no note. He described the operation, saying that the doctor first pulled teeth for the purpose

of starting the blood congealed in the womb, and afterward took an instrument, resembling a uterine sound, which was shown him, and passed it under the clothes; after a while something like a child came away. He denied knowing that the girl was pregnant, and although he etherized her, professed not to have understood any of the proceedings. He acknowledged removing the pot of blood, and said that the girl bled profusely. The doctor said that he had never seen the girl until the morning he was summoned. On first looking at her he discovered "that the blood was congealed in the womb" and he drew three teeth to start it. Failing in this he opened the womb with a female catheter, and delivery soon followed. The hemorrhage was not profuse. He made no examination any more than to discover that her bladder was full, and did not know that she was pregnant. He said that he had never had a note from the young man, and had not agreed to perform an illegal operation, nor had he done so. On receiving the proper authority I proceeded to make an autopsy. I present here the specimen, which will show better than any description the condition of things discovered.

Autopsy, fifteen hours after death. Body of a well-developed girl, somewhat emaciated, breasts enlarged, dark areolæ around the nipples, from which exuded on pressure a yellowish-white milky fluid. Abdomen distended, tympanitic, of a dirty brown color. A foul smelling purulent fluid issued from the vagina. On opening the abdomen the intestines protruded, being distended with gas, and much injected. The omentum was of a very dark color, and in the lower part of the abdominal cavity bound to the adjacent tissues by pretty firm adhesions. No free fluid in the cavity. Peritonæum opaque, and strongly injected. Fundus of the uterus six and one half centimeters above the pubes. Brain, dura abnormally adherent to the calvarium, vessels of the pia somewhat engorged; substance of the brain firm and rather anæmic. Otherwise not abnormal. Nothing particularly abnormal in lungs, heart, liver, kidneys, spleen, or pancreas. Intestines bound together and to the posterior surface of the uterus by firm adhesions. In the pelvis behind the womb there was found pus to the amount of about sixty c. cms. The cavity of the uterus measured ten cms. from the os to the fundus, and eight cms. in width. A ragged, irregular track or furrow was found extending from a point four cms. from the external genitals to the os. The mucous membrane in this track was wanting, and the tissues beneath ragged and sloughing; this furrow was the seat of two perforations of the vagina posteriorly, of a size varying from that of a pea to that of a filbert, with ragged and sloughy edges. The furrow terminated at a ragged, irregular opening, four cms. by five cms., embracing the whole of the posterior part of the cervix. The edges of this opening were gray and shredly, the whole being a large slough. This opening also was found to communicate with the encapsulated pus, before mentioned, and with the peritoneal cavity. The cavity of the uterus was lined with a brownish-gray shredly tissue, denser at the fundus, and floating up readily when the organ was placed in water, where was apparently the seat of the placenta. The ovaries were normal in size and bound to adjacent tissues by adhesions. In the left ovary was a yellowish oval body with cavernous centre, and scalloped edges, a corpus luteum, so called. Such were the anatomical appearances found on

autopsy. From them the following opinions were warranted: the woman had recently been pregnant, she had recently been delivered. Either before or at the time of delivery she had received severe injuries of the womb and vagina, which had taken on purulent and gangrenous inflammation. These injuries had caused peritonitis, this peritonitis had caused death by syncope.

The most probable view of the case seemed to me to be that the injuries of the vagina and uterus were caused by instruments used recklessly by an ignorant man, who, having lost his head at some real or fancied danger, attempted to forcibly dilate and remove a fetus from a uterus in which labor was already progressing. I believe that primarily an operation had been done, or drugs administered, and at length when labor had set in, finding there was an unusual hemorrhage, or wishing to get out of the woods as quickly as possible, he had torn the woman in the way described in his endeavor to effect delivery before the slowly dilating neck was in condition to admit it safely. This opinion was subsequently justified. There was an inquest and a verdict in accordance with the facts. The prisoners were held for the grand jury. They were indicted. On the day appointed a motion was made to quash the indictment on the ground that nowhere was it stated that the deceased was a woman. The judge granted the motion, and the indictment was quashed, thus illustrating again what to common-sense people seems the absurdity of laws, and how, as a rule, they are contrived so as to defeat justice rather than secure it. A new indictment was procured, and the case came to trial. Meanwhile the young man decided to make a clean breast of it, and the government used him as a witness. His story (admitting that he had lied while under arrest) was substantially as follows: He went to the doctor's office, and said, "Well, doctor, I've got a girl in the family way, six months along. Can you do anything for her?" "Yes," was the answer, "I can for fifty dollars." He, not being able to pay the sum at that time, gave his note for the amount. The next night he went with the deceased. The doctor gave her some powders, and the girl told him afterwards that a day or so later, at his office, the doctor passed an instrument up inside her. After that she had the cramps, as described, and he finally sent for the doctor, who came and performed some operation upon her, bringing away a child, which was a boy. I only propose, however, here to speak of the medical testimony on the side of the defense. Suffice it to say that the examination of the accused showed him to be a thoroughly ignorant, conceited, but cunning fellow. One of the experts testified with fairness. He was of the opinion that the girl might have had eclampsia; that all the wounds could not have been self-inflicted; that premature delivery was in general recommended for this trouble; this without stating the period of pregnancy. Another expert, who has figured largely in that line, gave the most extraordinary testimony that it has ever been my fortune to hear from the mouth of a member of the Massachusetts Medical Society. The unenviable notoriety he has gained by his testimony in grave cases, and the contempt he has brought the profession into by such conduct, make it worth while to give a sample. The statement of the accused as to the girl's condition when he entered the room was repeated to him, namely, "that she was lying on her side, her knees drawn up, and hands clenched, and groaning," and he was asked his opinion as to

diagnosis. The reply was, "I should have no hesitation in deciding that it was clearly a case of eclampsia." He testified that in eclampsia one could not perform venesection at first, and something must be done at once. That the disease was almost always fatal, and that if ether and bleeding did not stop it, the one thing to do was to deliver. That this must be done without regard to the term of pregnancy. He should do leeching and cupping, not venesection, because one could get a smaller quantity of blood. That in all cases the bladder should be emptied. He stated that some of the best authors advised delivery regardless of the period; when pressed for the names he could only give that of Barnes (who, by the way, does *not* recommend it). The wounds were, in his opinion, made by a sharp instrument, but might have been caused by the expulsion of a fetus. It was impossible to tell whether the womb of the deceased presented to him for examination was that of a pregnant woman or not. It might have been that of a fibroid tumor or a molar pregnancy. The time the doctor was there was proved, and this expert testified that the fetus could not be got out by forcible means in an hour and a half. Now, when a member of our State Medical Society, and one who has so far the confidence of the prosecuting officers that before this very jury he had, a few days before, been held up as an honest and skillful man, when such a man can with impunity go on the stand, and for money swear that the description of an ordinary labor pain was sufficient to convince him that the case was one of eclampsia; that little bleeding was better than much, thus justifying the tooth-drawing dodge; that delivery was the only thing, in face of the facts that it does not always stop it, and that artificial delivery must be resorted to in face of the success of ether and venesection; when he testifies as a matter of *fact* that the best authors advise this procedure, — when Cazeau, Leishmann, Schroeder, Playfair, Gooch, Winckel, Lee, Ramsbotham, Elliot, Murphy, Barker, Churchill, Siebold, Smith, Blundell, Dewees, Naegele, Hodge, and even Barnes himself, whom this expert quoted, not only do not advise but protest against it in the period before the eighth month in eclampsia, and many advise against it at any time, — when such a man can have the audacity to swear that the uterus I have shown you could not be pronounced that of a pregnant woman, when he can swear that the womb might be in that condition after the expulsion of a fibroid tumor, I say when a man can do *that*, and still retain his membership in our society, and gain credence in the courts, then it is time for a strict regulation as to medical expert testimony or to acknowledge that we *are* what we are represented, — members of the guessing profession, who can be retained on either side to swear to anything counsel may desire, provided we escape the statute for perjury by the slender pretext that it is opinion merely. The defense in this case was like that of the woman with the borrowed pot, who declared that she never borrowed the pot, that it was cracked when she got it, and that it was whole when she carried it home. It was proved by this expert that the girl was not pregnant, that being pregnant she operated on herself, that the doctor, who swore he never did it, did it as a justifiable measure to save life when eclampsia was present. The case was ably argued, and the jury, I am informed, at first stood eight to four for conviction. I am also informed that the foreman, a neighbor of the accused, had a dream showing

him how it was all done, and he, being the strong man, brought round the other eight, and a verdict of not guilty was rendered, and for the second time this abortionist went unwhipped of justice. My colleague testified to the fact that the accused had the reputation of being an abortionist, having had occasion to look up his record when he had brought him to book for a case very much like this. His dodge was in every case to do some legitimate operation like tooth pulling, and under the cover of that to do the abortion. Though it was a disappointment to see such a rascal go scott free, nay, be received with open arms, and be presented with a new horse and carriage, it was nevertheless a satisfaction to be informed, after the trial, by one of the counsel for the defense, that my own theory as to the crime was correct, and that the young man's story, except in minor details, was true."

DR. F. W. DRAPER said that the case reported by Dr. Harris was a good illustration of the difficulties attending the investigation of cases of criminal abortion, of the tricks of abortionists, and of the uncertainty of jury trials. But the most important lesson suggested was one pertaining to the evils and abuses of medical expert testimony. Here is a man, the defendant, with a crooked record, without credentials or recognition as a medical man, dismissed not long ago from the Boston University Medical School for misbehaviour, practicing medicine under authority derived from Buchanan's Philadelphia diploma factory, and now in court to answer a charge of the gravest nature, indicted for a crime whereby the lives of two human beings were destroyed. And the strongest allies and defenders of this man and of his practices appeared in the persons of two members of the Massachusetts Medical Society; two regular physicians; two medical experts. Their presence in court and their association with the defendant in a wholly voluntary relation opened serious medico-ethical questions as well as suggestive medico-legal ones. Would these gentlemen consult with this accused party in any of his clinical embarrassments outside the court room? if not, how could they consistently appear as his voluntary aids in this trial? The trial was a public one, and therefore Dr. Draper thought the acts of all connected with it were properly the subject of criticism, and, if need be, of censure. The character of the expert testimony had been sufficiently analyzed and described by Dr. Harris; but Dr. Draper differed from the reader somewhat as to the effect of the testimony, and the responsibility of the verdict for acquittal. The foreman of the jury may have had influence, but he in turn must have been influenced by the opinions expressed by the medical experts. The defendant was not the only one who was under obligations to the two experts who had helped him; for when the verdict was announced, every abortionist in Boston saw the effect on his own relation to the law, and on his chances of punishment if detected. Dr. Draper disclaimed any personal disfavor toward the medical experts alluded to, but he felt very strongly about the kind of testimony which they represented. The profession had come to expect such exhibitions as inevitable in the course of legal administration, and as probably incurable. But the evil was *not* incurable; many good remedies had been proposed. Suppose, for example, that the prosecuting attorney and the counsel for the defense had agreed upon any one of half a dozen well known specialists in obstetrics in this city, and had left all the technical medico-legal elements in the case to him to elaborate and to

present in evidence; or suppose, in default of such agreement, the court had appointed the expert in this case; we should then have had skilled medical evidence that would be disinterested, because there would be no temptation to partisanship; able, because it would be for the interests of both parties to secure the best; authoritative, because the expert would recognize his opportunity, as well as his duty, to give the latest and surest scientific dicta bearing on the case. So long as the profession showed itself indifferent to the matter of medical expert testimony, or hesitated, or neglected, to criticize and condemn bad exhibitions by its representatives in court, or had only occasional spasms of indignation, it need not count on any material help from the lawyers, or from any other source, toward promoting a reform which was not inferior to any now presenting in medical councils.

DR. E. G. CUTLER believed it had been made very evident by the remarks of the last speakers that some change was urgently needed. He thought that as Massachusetts had been forward in the reform of the coroner abuse, so now she should take the lead in this. He deemed it advisable for the Society to appoint a committee to confer with the other medical societies, with a view toward taking some measure to secure this much needed reform.

DR. W. F. WHITNEY said that such a perforation of the cervix as is seen here could have taken its origin from one of the slight tears which occur in a natural labor. By coincidence such a specimen was placed in my hands at about the same time as the specimen before us. This occurred in a case of normal labor where there had been no instrumental interference whatever. The facts which point to this perforation being the result of violence are first the immaturity of the child, the bones being soft and yielding and not likely to produce laceration, which could be the starting point of the perforation, without violent mechanical means had been employed at the same time as the labor; and secondly the lacerated furrow of the vagina, which could have only been made by some instrument roughly applied.

DR. BLODGETT, in referring to his experience with medical experts, said that he was acquainted with two whose opinions were highly valued in the courts. One of these was usually on the side of the government, and in several cases of trial for murder the conviction of the prisoner had probably been largely due to his testimony. This expert showed to Dr. Blodgett some specimens obtained from dried blood stains found on the clothing of the prisoner, on wood and other objects. Dr. B. asked as to the method of restoring the dried blood corpuscles, and on this being described inquired if the process employed would not cause decomposition of the corpuscles. The government expert admitted that it would, but said that by examining the specimen at just the proper moment this error might be avoided. In face of the acknowledged difficulty in deciding whether blood corpuscles were derived from the human subject, or from some other mammal, even under the most favorable conditions, this expert was ready to swear away a man's life, relying upon a method which he himself acknowledged false. This same so-called expert also showed Dr. Blodgett a slide, in which he claimed to have discovered a new form of coagulation of the blood, not mentioned by any of the authorities which he had consulted, and which was to make the discoverer famous. Examination showed the coagu-

lum to be a typical specimen of the structure of pine wood. As still another instance of his ignorance Dr. Blodgett spoke of the case of a woman who had died under suspicious circumstances during the time this expert occupied a position as coroner. After an autopsy he decided that death had occurred from criminal abortion and returned this verdict to the district attorney. He brought a specimen of the kidney, uterus, and liver to the speaker for microscopic examination. The wall of the uterus was not thicker than normal. The liver was the seat of complete fatty degeneration of the whole parenchyma, so striking in degree that Dr. Blodgett remarked that he should have suspected acute phosphorus poisoning. A few days after the coroner told Dr. B. that he had decided it to be a case of phosphorus poisoning, as he had found a partially empty box of rat poison in the house.

Dr. DOHERTY said that he was one of the so-called medical experts in this case, but that he had not taken the position in regard to it which Dr. Harris had stated. The two experts for the defense maintained that the uterus could not be emptied in from forty to forty-five minutes; the government expert admitted this. Their position was, that it was physically impossible for a man to etherize a woman, extract three teeth, and effect delivery (especially in a case of mal-presentation, as was supposed by the government) in the time that the defendant was in the house. Dr. Doherty said that there was no doubt that labor was in progress at the time the doctor was called in; he thought the history of the case would establish this as a fact. He questioned as to whether the wounds might not have been either inflicted by the woman herself or by the landlady, who was not put on the stand by the government; that probably a knitting needle bent upon its If was employed. It was admitted by the government expert that the injuries could not have been caused by a uterine sound. The speaker thought the great trouble in expert testimony was that there was an attempt to establish the possible extremes, rather than the probable mean.

Dr. HARRIS said that he had not intended to do Dr. Doherty any injustice, and that he thought the society would bear him out in the statement that he had spoken in the most complimentary manner of the fairness exhibited by Dr. Doherty in his testimony. He could only add that at the conclusion of the trial, one of the counsel for the defense admitted to him that the theory of the prosecution was correct in every respect.

Dr. HUNT read a paper, entitled *Principles of Medical Reform*. He said that one of the most discouraging studies for the physician in Massachusetts is the history of medical education and organization in this State. There have been many reforms, but they result in nothing lasting. The history of our medical school is a history of reform efforts. The school began its reform in the eighteenth century, it was reformed again early in this century. There was a reform in 1846, and still another in 1870. The chief result of all the reforms has been new buildings. When President Eliot points to-day to the fact that as a result of the reform in 1870 the students are scarcely to be distinguished from the students of the other departments of the University, he merely draws attention to the results of the high price of instruction and the long term of study; these bring together students better able to pay the price, and afford the time; also students more patient in cramming for examination. The degree bears wit-

ness to all these things, and he who believes in the means may accord the degree a higher character; on the contrary, neither the facts nor the degrees are worth much as proofs of sound professional acquirements. The chief aim of reform should be to make better doctors; that is, men truer to the claims of scientific research for the good of the future, as well as better able to give value received for the fee in the present. Our colleges have taught us by means of their graduates that degrees will lie; this is truer in medicine than in academic pursuits. Yet the medical school makes the degree its chief care, as the English schools have always done and are now doing. It might have done better to imitate the German method of selecting teachers and inciting students to better efforts; this latter method has surely succeeded better in medicine, at least. Our efforts to raise the standard and to elevate the character of the degree have placed many burdens upon the student but they have not affected the method of educating, nor have they reformed the faculty. Time alone seems to furnish all remedies for disease in the body; the present method seeks to hold the student to his work by examination; need it be said that this favors cramming rather than habits of research, habits that would make our graduates students after leaving the school? Our profession needs more of the university freedom that we hear so much of in Germany; a freedom that leaves the promotion of teachers and students to competition; that selects teachers according to proven skill in teaching, and not by the arbitrary standards of a clique held together by obsolete conceptions of professional needs and requirements. It seems strange at first to look to autocratic Germany, rather than liberal England, for our model, but in the last great European reform epoch, England turned her attention to trade and politics, while Germany, to turn attention from these matters, left her students a free field for reform efforts in the universities. As a result we see democratic ideas and methods in Germany's educational policy and the same ideas and methods in English trade and politics. Our redemption from much corruption will be obtained by copying each where they afford us the better model.

Dr. H. I. BOWDITCH trusted that Dr. Hunt's paper would not be allowed to pass without free discussion. He would like to know a little more definitely exactly what changes the reader would propose. He thought that the quality of medical education in Boston had decidedly improved in the last few years, and it was incumbent on any one who thought it could be still farther advanced to state freely in what way he believed it could be accomplished.

In reply to Dr. Bowditch, Dr. Hunt said that his paper was upon the principles of reform; consequently he had not touched on details. He thought, however, anatomy might be instanced as affording a field for practical reform effort. We hear a great deal of lack of material for dissecting; social conditions make this material common in Europe. Might the school not teach methods and principles of anatomy during the first year by means of domestic animals; and at the same time gain an opportunity of associating embryology, histology, and anatomy, in a cheap, practical, and easy manner? subjects might be used more freely later in the course. Anatomy should be studied every day during the student's stay in the school and not finished by an examination, even in the second year.

Dr. BIGELOW said he believed that the Faculty

of the Harvard Medical School were glad of free discussion as to the best methods of medical teaching; whether it relates to what exists, or what may be supposed to be needed. In looking at the late history of this school the point that presented itself most distinctly to his mind was the great improvement that had been effected in the quality and amount of medical education in Boston; much more instruction is given by the teachers; much more is acquired by the students; the quality of this learning is better to-day than ever before. He admitted a difference between the methods employed here and in Germany. The latter may be in some respects better, but this arises from the different conditions that exist there and here. As to the claim that anybody who had material should teach under the auspices of the university, there is this to be said: if we want a good corps of teachers, we must pay for them. In Germany pay is guaranteed by the government, which also retires its professors on salaries, here there is no pecuniary inducement offered to a teacher unless he can attract students who will pay him, or the university for which he teaches, — and students cannot be relied on to support the best schools; the poor schools often attract a considerable number of students. In the medical school, we attempt much the same thing as in the medical society; namely, a selection, based on scientific quality, but that is the extent of our exclusiveness; the object of the school is not to sustain teachers (we all know their salaries here are small enough) but to use an American way of sustaining a standard of teaching. He admitted his belief that there should be a constant vigilance to secure all the good teaching that could be procured, that it should be allowed an opportunity somehow, here as in Germany, to show itself. So far indeed, though there has been no system, this has practically been accomplished. But an assured system in the future would lead to further competition, and the continued success of the best talent. Another difficulty we have to contend with in this country is the fact that we have only a small class of teachers here, largely represented abroad, who devote their whole lives to science. Here medical men are eager to practice their profession; their aim is the degree, and the quickest way of getting it. There is a considerable class of men abroad who teach special science and attract a great number of students. We meet this disadvantage in part, by teaching their doctrines. The scientific atmosphere is obviously not the same, and yet a scientific future is before us not remotely. Dr. Bigelow thought the medical school was doing well under existing circumstances, further improvements would come in time. We need not be dissatisfied with our progress, the medical profession ought rather to be grateful to those who attempted this advance in medical education; which he said with less hesitation because he himself had no hand in introducing the graded system, one of its principal features, into our medical school.

Dr. HUNT insisted that Professor Bigelow had missed the point of his paper. There is no doubt that the school does more work; the question is, Does it fit better for the practice of medicine? Dr. Hunt claimed that it does not fit by present methods as well as it did by those which obtained before 1870.

Then, the student went from anatomy and physiology to surgery and medicine. He was continually reminded of the connection between the theoretical and the practical parts of the discipline; the student was left greatly to himself; it was left for self-interest

to prompt him to make the best of his opportunities; manliness was developed. At present, a cut-and-dried system is forced upon each student; he is held to it by examinations; he naturally takes to cramming, — a process more injurious in medicine than a considerable degree of neglect of method would be. In answer to Professor Bigelow's statement that the State paid the teachers and scientific men in Germany, Dr. Hunt stated that human nature is much the same the world over; if the university would open a free competition for positions of honor, and make good work the only consideration, it would give a practical value to such work here, as it has done in Germany, naturally, more work would result. All should have an opportunity, that the hopes and ambition of all may be stimulated; as it is now, only a favored few can start in the race. They may be competent, but they have no opportunity to prove it. Give all a chance; the favored ones may win, then, having earned their positions, they will secure more self-respect and honor from the profession. It is well, also, to remember that the most learned and the most eminent medical men are not necessarily the best teachers. Teaching requires peculiar abilities. The special requirements of the medical teacher can be proven only by actual experiment; hence, there should be free right of teaching; the best should be selected from the masses by a process of natural selection.

Dr. BIGELOW remarked upon the first point, that different students need different systems. No college could prosper that should adopt a system absolutely different from that of every other college in the country. Harvard had raised the standard of teaching and maintained it at a higher point than any other school. It had not retreated from it. Progress cannot be pushed faster than is wise.

Dr. HARRIS exhibited a specimen showing the result of a Barton's operation, performed twenty-five years ago. There was originally an ankylosed knee-joint, the lower leg being flexed on the thigh at an angle of seventy degrees.

Dr. HODGES said that the boy's case attracted a good deal of attention at the time, when the operation for the relief of ankylosed joints was comparatively infrequent. The usefulness of the limb after this operation was very considerable. This operation, at the present time, is rarely done, since the present methods of excision give more satisfactory results, there being less deformity and a diminished death-rate.

Dr. G. W. GAY reported a case of vesico-vaginal fistula, with entire absence of the urethra. The hole into the bladder would admit the forefinger, and was located just behind and beneath the pubes. The mucous membrane was natural, and no folds or fissures existed to show that there had ever been a urethra. The operation performed was to remedy the incontinence. A flap of mucous membrane was dissected up and brought forward. The posterior margin was united to the posterior margin of the fistula, thus forming a urethra, without a sphincter; by wearing a pad, arranged so as to bring a certain amount of pressure over the opening, the urine could be retained for several hours, the condition of the patient being thereby much ameliorated.

— A cremation society has been organized in New York city. On the evening of March 24th a large number of the members listened to a lecture on the disposal of the dead, at Cooper Institute.

RHODE ISLAND MEDICAL SOCIETY.

A quarterly meeting of the Rhode Island Medical Society was held in Providence, March 16, 1881. The president, Dr. Charles O'Leary, in the chair.

On recommendation of the board of censors, Drs. G. H. Harris, of Greenville, M. J. E. Legris, of Centreville, and F. B. Fuller, of Pawtucket, were elected to fellowship.

Dr. T. Newell, chairman of the library committee, announced that hereafter the library will be open daily from twelve to one o'clock.

Delegates to the American Medical Association were elected as follows: Drs. A. Ballou, of Woonsocket, W. J. Burge, of Pawtucket, E. P. Clark, of Hope Valley, A. C. Dedrick, of Centreville, G. W. Jenckes, of Woonsocket, J. Kenyon, of River Point, D. King, of Newport, A. A. Saunders, of Carolina Mills, and Drs. G. W. Carr, J. W. C. Ely, A. E. Ham, C. H. Leonard, J. W. Mitchell, R. F. Noyes, A. Remick, A. E. Robbins, J. W. Sawyer, and O. C. Wiggin, of Providence.

Dr. G. A. Burg presented a paper on the Chemical Analysis of Urine, and demonstrated the tests for the chlorides, albumen, sugar, bile, etc.

Dr. Peabody, a veterinary surgeon, was introduced to the society, and reported a case of embolism of the aorta and iliac arteries of a horse, and exhibited the specimen.

Dr. C. A. Maryott read a paper on the use of obstetric forceps, and advocating the administration of belladonna for three to six weeks previous to confinement, with a view to rapid relaxation of the os.

Dr. Capron deprecated an early resort to instruments. Children do not often die from rigidity of the soft parts, and he doubted whether uterine contractions endanger the child by interfering with the circulation of the placenta. So long as the pains intermit, and the head is not locked at the superior strait, it is better to wait. In cases of lingering labor, due to stubbornly hard os, the local application of belladonna is valuable.

Dr. Cone reported a successful use of extract of belladonna and cosmoline applied to the unyielding os.

Dr. Tyng observed that in the Woman's Hospital in Philadelphia this local use of belladonna ointment was frequently followed by ruptured perineum, and considered the hot douche preferable. The advantages claimed for the hot douche are uniform relaxation of all the soft parts, cleanliness, and less risk of hemorrhage.

Dr. O. C. Wiggin preferred the use of morphia for protracted rigidity of the os. Dr. Burge had found ether a valuable relaxing agent.

Dr. Noyes reported the following case: A man, aged twenty-five, was caught in a revolving shaft, and sustained a simple fracture of the humerus in its upper third. He was attended by a "natural bone-setter," who applied an external angular splint and a bandage, and neglected to see the case again. Six weeks after the accident Dr. Noyes was consulted, and found the splint and bandage loose, very little callus at the seat of fracture, and no union.

Under ether the ends of the bone were terribly rubbed together, and the whole limb put up in a plaster bandage. In five weeks free motion was permitted at the elbow, and two weeks later the patient resumed work with a strong arm.

Dr. Caswell considered this a case of delayed union rather than of ununited fracture. He had seen two cases of the latter condition. One, of the femur, was encased

in plaster for five months without benefit. The patient refused an operation and got about with crutches.

Dr. T. W. Perry reported the case of a physician who had an ununited fracture of the tibia. He wore a firm leather splint, and was able to attend to practice. Two years later he was thrown from his carriage and injured the same leg the second time, when the bone united firmly.

Dr. Caswell reported two recent hospital cases:—

(1.) A young man was admitted to Rhode Island Hospital, having a loose cartilage in each knee-joint. The operation for removal of the cartilage was first done on the right knee with all the precautions of Listerism, and was successful in every way. Two weeks later the cartilage in the left knee was removed without difficulty, and in ten days the patient was discharged.

(2.) A case of litholopaxy. The patient was a young man with a capacious urethra. Fearing a hard stone Dr. Caswell used a strong Thompson lithotrite. The calculus was composed of oxalate of lime, and weighed twenty-four grains. Time of operation, forty-five minutes. Patient discharged on the tenth day.

New Instruments.

A NEW NEEDLE-HOLDER.

BY W. THORNTON PARKER, M. D., PLYMOUTH, MASS.

MESSERS. GEORGE TIEMANN & COMPANY, of New York, have made for me a needle-holder which may possibly be acceptable to others in the profession, and, on this account, I venture a short description of it.

The needle-holder is made of metal, nickel-plated.

It consists of a cylinder for holding the needles and a simple attachment for firmly securing the needle in a forcep-like grip for operating. This holder can readily be carried in any pocket-case of instruments. It saves the trouble of searching for scattered needles, and is of service to the operator in enabling him to take a *firm* stitch and to hold the needle *securely*. It is needless to say here that it is important to sew quickly, and to be able to bring the flaps *nicely* together. In sewing without a needle-holder the surgeon, by reason of the restlessness of the patient, rapidly losing the effect of the anæsthetic, and also on account of the slippery condition of the operator's hands and fingers, not to speak of the weariness and tendency to cramp in them, finds it often very difficult to sew steadily, and, *perhaps*, on that account, may fail to make a satisfactory stitch, the needle repeatedly slipping. These accidents may cause the patient considerable suffering, and I have reason to believe are of frequent occurrence. If an apology is needed for this simple little appliance, I would say that anything which *aids* in rendering operations easier, or contributes to the comfort of the patient, is worthy of notice. I find the instrument useful, and hope that others may also. The needle-holder necessarily carries only the straight and the slightly bent needles, which are commonly used. Some of the needles contain eyelets at the points, which are often desirable. Other needles, of great curve can be carried separately in the pocket-case; but in sewing the needle-holder will be found convenient for all kinds.

Medical and Surgical Journal.

THURSDAY, APRIL 7, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

ISAAC RAY, M. D., LL. D.

No medical man during the present century has more deservedly left behind him at his death a world-wide reputation for wisdom, theoretical and practical, grandeur and yet simplicity of character, than our distinguished fellow countryman, Dr. Isaac Ray, who died in Philadelphia, March 31st, in the seventy-fifth year of his age. Though for many years of his life a resident of other States he was a native of Massachusetts, having been born in Beverly, in 1807. He studied medicine with the late Dr. Shattuck, in Boston, but graduated at Bowdoin College, and commenced the practice of medicine at Portland, Maine, in 1827, afterwards removing to Eastport. He early turned his attention to the study of mental diseases, and in 1838 published his *Medical Jurisprudence of Insanity*, a work which has passed through five editions, and is the best which has ever been written on this subject in the English language. He was appointed Superintendent of the State Hospital for the Insane, at Augusta, Maine, in 1841, and remained in charge of that institution till 1846, when he was elected Superintendent of the proposed Butler Hospital for the Insane, to be located at Providence, R. I., but then unbuilt. Dr. Ray spent several months in Europe carefully studying mental diseases and hospital work, and on his return, with the assistance of his life-long friend and confrère, Dr. Bell, of the McLean Asylum, he planned the Butler Hospital, and immediately entered upon the work of superintending its construction, every detail being finished under his personal supervision. From that time till the day of his death he was personally identified with all its interests. After twenty-one years of service his health necessitated his resignation, and he removed to Philadelphia in 1867.

He was one of the original members of the "Association of Medical Superintendents of American Institutions for the Insane," and was its president from May 22, 1855, to May 17, 1859. He received the degree of LL. D. in 1879 from Brown University, and was made an honorary member of the Medico-Psychological Society of London in 1880.

In addition to his master work, the *Medical Jurisprudence of Insanity*, he published in 1863 *Mental Hygiene*, a practical and popular work, and in 1873, *Contributions to Mental Pathology*.

His annual reports while Superintendent of the Butler Hospital were finished, learned productions, and discussed the whole ground of treatment of disease

and of hospital construction. Since his retirement his pen has rarely been idle, and he has written for many prominent medical and literary journals. He was the author of innumerable reviews and of many papers read before the Rhode Island and Pennsylvania medical societies, and the Association of Superintendents. It can be truly said that he never wrote upon any subject until he had thoroughly digested it, but when he had done so he believed it his duty to communicate his views to others. There was a conciseness and thoroughness, a purity and an earnestness, in all his writings which made them as attractive as a well written novel, and which carried conviction to readers or hearers.

As an expert in court his strength and directness, his clearness and simplicity were even more apparent. Thoroughly honest, incapable of partiality or unjust prejudice, he despised the trickery and shallowness of much that is called the practice of law. His opinions, judiciously and deliberately formed, and weighed in the balance of his discriminating mind, became firm convictions. He was always open to argument, but having once decided he was firm as truth itself, and no cross-examination or brow-beating could change his views. As a medical witness he was unsurpassed.

As the superintendent of a hospital he had great personal power; no one familiar with the Butler Hospital can fail to see in its arrangements the lasting impress which he has left upon them. To his great knowledge of mental disease he added firmness, patience, and the utmost kindness. He was as thoroughly the friend of the patients and his subordinates as he was the chief executive of the institution, and his personal character, his long experience, and his judicious counsels have helped many a darkened, deluded mind back to life and happiness.

By nature and training he was conservative; but his conservatism was not of the kind to shrink from real improvements. It demanded a deliberate judgment upon so-called advances in medicine and in the treatment of the insane; but all real progress found in him a most earnest advocate. No one can ever estimate the influence of his powerful pen upon the subject nearest his heart in the quiet and retirement of his home after the more active public duties of his life were over.

He was a person of few words; but in his own home and among his intimate friends and acquaintances he was social, cheerful, and very entertaining. No one could spend an hour with him without profit.

As a friend he was cordial and unwavering, never hesitating to give advice or to make corrections if asked, but always ready to encourage and help. Hundreds of young men have looked to him for counsel, and never have been disappointed. In all our institutions for the insane his influence has been, and will be, felt through his writings long after the generations who have known him personally have passed away.

To such a man death comes only as the completion of a life work, and has no terrors. Clear and strong in his religious convictions, as in all others, with un-

dimmed intellect, though wasted and feeble in body, he looked calmly to the end as a culmination of his labors and an entrance upon a well-earned rest.

Grand, simple, honest, warm-hearted man! may we, by following ever so humbly in his footsteps, render to our day and generation a service more useful and more efficient because of his work and his example!

ON TO RICHMOND.

THE next annual meeting of the American Medical Association is to be held at Richmond, Va., on the third, fourth, fifth, and sixth of May. It should be in many respects an enjoyable occasion, and there is reason to believe that some valuable papers will be contributed, which we hope will not be buried until the publication of the Association's Transactions, when the interest which they may excite will, in a great measure, have subsided.

The season of the year is peculiarly favorable for a visit to Richmond, the northern visitor being twice blessed, — directly in the earlier southern spring which he secures, and indirectly in the avoidance of the tedious vernal germination at home.

To physicians resident in New England the Boston, Norfolk, and Baltimore Steamship Line offers attractive facilities for reaching Richmond. The round-trip ticket from Boston to Richmond will cost \$16.50, and this includes meals and staterooms between Boston and Norfolk. Any one wishing to attend the meeting of the Association, and desiring the invigorating tonic of change and freedom from care without the fatigue of travel, will be apt to find it in the four days' trip to and from Norfolk, especially if fortunate, as at the end of this month or the beginning of next he is likely to be, in having a comfortable run around Cape Cod and over the Shoals.

MEDICAL NOTES.

—The *Lancet* considers the secondary suture of nerves one of the great advances in surgical therapeutics. Quite lately it has been practiced, not with uniform success, yet with most encouraging results. The best test cases are those of union of severed motor nerves, for the return of sensation in parts supplied by a divided and then sutured nerve is open to another explanation than that the nerve trunk has again become capable of conducting sensory impressions. For this reason a case of Langenbeck's, of secondary suture of the musculo-spiral nerve, is very valuable. A laborer, thirty-one years of age, received a severe contusion of the outer side of the right arm below the middle, which was attended with paralysis of the extensor muscles of the forearm and hand. An abscess subsequently formed and was opened. Two and a half months after the injury, as the paralysis continued, Langenbeck cut down upon the divided nerve, freed its ends, which he found two centimeters and a half apart, and united them by a catgut suture. Nine-

teen days afterwards the extensors reacted to the induced current, and after a month and a half considerable active extension movements were possible. Mr. Hulke has brought forward at the Clinical Society a case in which he had united the cut ends of the median nerve nearly six weeks after the injury, and another case in which he practiced a similar operation on the ulnar nerve fifteen weeks after division, and in each instance there was distinct evidence of restoration of function. Esmarch and Létiévant have each had a case of suture of the musculo-spiral nerve, the former successful. These and other like cases afford great encouragement not only to unite by suture the cut ends of nerves in recent wounds, but, where necessary, after cicatrization is complete.

—The Hon. Lewis Wingfield is engaged, it is said, on a thrilling story concerning lunatic asylums in England, under the title of *The Haven of Urest*, which will appear in prominent papers. Even in the country to whose system of insane asylum management appeal is so frequently made there seems to be a chance for the asylum agitator.

—Rules for ready metric writing. For fluid mixtures: Write for the same number of GRAMMES of each article as the number of grains or minims in each single dose of the article. Add sufficient vehicle to make a SIXTY GRAMME mixture. A teaspoonful will contain the proper dose. For pills or powders: Write for the same number of GRAMMES of each article as the number of grains in each single dose of the article. Divide into fifteen pills or powders. Each will contain the proper dose.

NEW YORK.

—A lioness in Barnum's show at the Madison Square Garden was recently safely delivered of a pair of fine whelps, and these, with the baby elephant, which is still unweaned, now form an interesting feature of the exhibition.

—At the last meeting of the County Medical Society Professor Alfred L. Loomis read a paper on *The Causes of Death in Acute Pneumonia*. After quoting elaborate statistics to show how very variable was the rate of mortality in this disease, both in hospital and private practice, he went on to speak of its nature. While not prepared to fully accept the view of Jurgenson, that it was an infectious constitutional affection, he could not deny that there were many facts which seemed to lend it support; but for himself he preferred, with his present light, to regard pneumonia as occupying a middle position between an essential febrile disease and a local inflammation. Blood-poisoning was undoubtedly a very frequent and prominent element in it, and failure of the heart, the most common cause of death in the disease, was generally to be ascribed to the action of the sepsis upon the nerve-centres. Pneumonia was exceedingly apt to prove fatal when complicated with pleurisy, alcoholism, Bright's disease, endocarditis, or severe malaria, all of which tended to enfeeble the action of the heart. In speaking of the treatment he spoke with great confidence of the efficacy of the very free use of morphia

by hypodermic injection during the first four days of the disease.

— At the stated meeting of the Academy of Medicine held April 7th, Dr. Isaac E. Taylor read a paper on Spontaneous Version and Evolution of the Fetus in Shoulder and Arm Presentations, and the Management of Such Cases Without Sacrificing the Child. On the same evening the annual commencement of the Columbia Veterinary College and School of Comparative Anatomy was held at Chickering Hall, when degrees were conferred upon a class of nine students, and an address to the graduates was made by Dr. T. E. Satterthwaite.

— Deaths from trichinosis seems to be increasing in frequency. The latest case is reported from Hoboken — that of a young German woman who had been eating raw ham and sausages. A microscopic examination of the muscles showed the presence of the trichinae in great numbers. The husband of the victim was also attacked with the disease, but recovered. The physician who was in attendance states that during the last twenty-six years he has seen sixteen cases of trichinosis in Hoboken, but the present is the only one that has terminated fatally.

— Typhus fever, which had diminished to such an extent that only five cases were reported during the week ending March 26th, seems again on the increase, and during the last few days as many as six or seven cases per diem have been reported. In the meanwhile the health department have been using every precaution to check the spread of the disease, and a special corps of inspectors have been visiting the lodging and tenement houses under the direction of the sanitary superintendent. Their reports are said to be generally encouraging, showing that while the cheap lodging-houses are as a rule overcrowded, they are for the most part kept clean and otherwise in a good sanitary condition. At the last meeting of the Board of Health the sanitary superintendent reported that there were at the present time fifty-one typhus fever and ninety-one small-pox patients in the hospitals on Blackwell's Island.

— A petition signed by the presidents of the various medical colleges and societies, and a number of other prominent physicians, urging the passage of the bill to secure the registration of plumbers and the inspection of plumbing and drainage in New York and Brooklyn, has been sent to the speaker of the Assembly at Albany. The bill has already passed the State Senate.

— A woman, sixty-one years of age, who had become partially insane on account of pecuniary losses, has just died in this city of voluntary starvation. For three weeks she refused to take any food, and during the last nine days of her life abstained from water as well as food.

— The St. John's Guild has now received sufficient money to enable it to begin the building of a seaside nursery at Cedar Grove, Staten Island, which has been for some time in contemplation. Into this will be received from the Floating Hospital such sick children, with their mothers, as are most in need of more fresh sea air than a single day's excursion can afford. The building is to be completed by the first of June.

Miscellany.

ABDOMINAL SURGERY.

WE are very glad to publish the interesting account of Dr. Burnham's achievements in the practice of abdominal surgery contributed by Dr. Irish; and we regret not having been cognizant of the fact, somewhat buried in the Transactions of the American Medical Association, and now for the first time brought to our notice, that to Dr. Burnham the credit of having been the first surgeon on record to successfully remove the uterus and ovaries may be attributed. The information afforded by our correspondent suggests that the above mentioned transactions may be better worth reading than we had hitherto imagined. Our readers will have noticed that the "omission" of the name of Dr. Burnham from our short list of those authors who have contributed by the publication of their experience to the secure establishment of ovariectomy and of the kindred operations is amply accounted for by the circumstance, acknowledged by our correspondent, that Dr. Burnham has hitherto neglected to publish his ovariectomies, either collectively or in series, only a few of these cases having been reported from time to time in the medical journals. This unusual reticence also explains the absence of any mention of Dr. Burnham's name in connection with the history of ovariectomy in such works as Dr. E. R. Peaslee's Ovarian Tumors and Ovariectomy, and Dr. T. G. Thomas's Treatise on the Diseases of Women. Dr. Burnham having thus refrained from publishing his experience and his results, the claim now advanced in his behalf by Dr. Irish, that to him more than to those mentioned in our article is due the present establishment of the operations of ovariectomy and hysterectomy, cannot be allowed. If Spencer Wells had contented himself with merely performing his operations, without taking the pains to enlighten the profession with regard to his methods and results, the medical world would have been little or none the wiser, and he himself would not now occupy the conspicuous position in relation to ovariectomy which will cause his name to remain forever one of the most illustrious in the history of surgery. — ED.

MR. EDITOR, — In reading the résumé of the rise and progress of Abdominal Surgery, as presented in your interesting editorial of last week, I noticed the omission of the name of one man, and that a surgeon of Massachusetts, to whom more than to many others mentioned by you in this article the present important and established position of the operations of ovariectomy and hysterectomy is very deeply indebted. I refer, of course, to Dr. Burnham, of Lowell. With your permission I will invite your attention briefly to a few facts in the history of these operations as connected with the work of Dr. Burnham in this department of surgery. Down to the year 1851, besides the series of ovariectomies by McDowell there had been, as far as known, thirty-two operations, and these had been performed by twenty-four different surgeons, or about that number; therefore the great majority of these surgeons had performed the operation but once. So disastrous, as a whole, had these cases been that the operation now rested under a cloud of disfavor, greater, if possible, than at any time before since the days of McDowell.

It was in this year of 1851 that Dr. Burnham performed his first operation. So great was the opposi-

tion to ovariectomy among the medical profession that this, joined to a certain amount of personal prejudice, went so far as to threaten him with legal proceedings in case the patient died. He performed the operation, however, and the patient recovered. Within a brief period after this first case he performed three additional operations, with two recoveries, that is, in the first four cases he had lost but one patient, and since this time he has been operating continuously, until now the whole number of cases is two hundred and fifty, of which the successful cases are not less than seventy-eight per cent. Dr. Burnham's rule of action has been to operate on all cases of ovarian tumors, even though the patient's condition seemed a desperate one, and to this rule he has made very few exceptions from the time when he began to perform the operation. Therefore this series of two hundred and fifty ovariectomies has embraced more than the proportionate number of severe and formidable cases, and when we consider that many of these operations were performed when as yet but little had been written or done in abdominal surgery, and when nothing was known of what we now consider indispensable antiseptic precautions, I think you will agree with me that that member of our profession who has done so much for the operation of ovariectomy is entitled to recognition and high consideration as being, with two or three other American surgeons, largely instrumental in changing the operation from a condemned to an approved one. A few of these cases have been reported from time to time in the medical journals, but as most of them have not been so reported I have given you the number of Dr. Burnham's cases of ovariectomy and their results.

In another department of abdominal surgery, to which I would call your attention, namely, removal of the uterus by laparotomy for fibroid and fibro-cystic disease, I would again bring to your notice Dr. Burnham's work. He was the first in the world who removed the uterus through an abdominal section, and saved his patient. This case you will find referred to in Ziemssen's *Cyclopaedia of Medicine*, and in the *Transactions of the American Medical Association* for 1878 a full report of the operations and the result. In the same article with this report are the histories of fourteen other cases in which he had removed the uterus and both ovaries.

In this brief and hurried note I have simply purposed to summarize in the fewest words possible the contributions to the advance of abdominal surgery at the hands of Dr. Burnham. I hope that even this meagre account may be of service to you in the continued discussion of the subject of your editorial article.

JOHN C. IRISH, M. D.

LOWELL, April 4, 1881.

THE ANTIQUITY OF DRAINAGE-TUBES.

MR. EDITOR, — The writer of the note published in the *Boston Medical and Surgical Journal* of February 24th (from the *British Medical Journal*), respecting the Antiquity of the Drainage Tube, has evidently overlooked the writings of that old master of surgery, Ambrose Paré. Repeated references are made by Paré to the use of "hollow tents," and on page 299 of the edition of his writings translated by Thomas Johnson, and published in London in 1649, he gives an illustration of these, with the comment that —

"The Reader must note that the pipes that are fit for this use, need not have so many holes as these here express; but only two or three in their ends: for the flesh growing and getting into the rest, make them that they cannot be plucked forth without much pain."

Speaking of the treatment Of Wounds made by Gun-Shot, Paré writes: —

"For this contained humor causeth an unnatural tension in these parts, and taints them with superfluous moisture, whereby the regeneration of flesh is hindered; for that every ulcer as it is an ulcer, requires to be dried, in Hippocrates' opinion. Many also offend in the too frequent use of Tents; for as they change them every houre, they touch the sides of the Wound, cause pain, and renew other malign symptoms; wherefore such ulcers as cast forth more abundance of matter I could wish rather to be dressed with hollow tents, like those I formerly described to be put into Wounds of the Chest."

On page 785, describing his treatment of Lord Annet, which would appear from the context to have been in 1569, shortly after the battle of Montcontour, Paré says: —

"I applied to mundise and drie the spongie and loos flesh, bolsters; at the bottom of the sinuosities, hollow tents of lead, that the *Sauies* might have passage out."

In the account of the same case the reader will find a description of a pretty good antiseptic dressing; and I will trespass on your patience by giving another extract from this very interesting case, which will serve to show the ingenuity of this great man: —

"Besides one may caus it to rain artificially in pouring down from som high place into a kettle, and that it may make such a nois that the patient may hear it, by these means sleep shall be provoked on him." Sincerely yours, F. A. CASTLE.

102 EAST FIFTY-SEVENTH STREET, }
NEW YORK, April 4, 1881. }

To the very interesting communication of our correspondent we append part of a letter from the *British Medical Journal*, brought out by the note which we copied from that journal: —

"If the gentleman who writes on this subject in the *Journal* of December 25th will turn to the *Lancet* of May 3, 1879, page 650, he will find the very identical passage about drainage-tubes he quotes from the *Memoirs of Captain Crichton* reproduced by me, *totidem verbis*, in this same connection. If he will read on further, he will further find that a drainage-tube, or something so like as to be indistinguishable from it, was used three hundred years ago by his physicians during the last illness of Philip the Second, King of Spain. The words describing this contrivance occur in a very rare book, entitled *De Felici Excessu Philippi Austriaci, Hispanarum Regis*. *Scriptis Hispanice Cerverra Turrianus, Capell Reg., etc.* They run as follows: 'Deinceps ciendo puri quo Mane et Vespere Scutellæ duæ replebantur, ut testatur Garcias de Onante, *Chirurgicâ fistulâ opus erat, quæ eademmodum locis remotis saniem educeret.*' Subsequently, for the purpose of withdrawing the pus, with which two porringers were filled morning and evening, his (Philip's) attendants required or employed, as Onante testifies, a surgical tube or pipe, which would convey the discharge from the remote parts.' If the classic tongue of Cicero, and of Horace, of Thomas à Kempis, and Father Prout — a knowledge of which has ever been to me a source of pride and pleasure — has not altered its complexion

since I was at school, these words mean a drainage-tube, and nothing else. Their etymology necessarily implies as much, especially so the words 'ciendo' and 'educeret,' and that the pipe or tube they indicate was used with this view cannot be doubted. If this be so, as it unquestionably is, why, I ask, all the fuss that is made in these days about its discovery? In my humble opinion, many, if not all, of the so-called surgical discoveries of modern times were known ages ago, — before the great-great-grandmothers of their respective votaries were born."

ANSWER TO "QUERIST."

MR. EDITOR, — In answer to "Querist" in your JOURNAL of April 7, 1881, I would say, that in the discussion which followed the reading of my paper on Soluble Compressed Pellets for Hypodermic Use¹ Dr. John B. Roberts announced the fact that salicylic acid, when added to solutions of morphia, would prevent the formation of fungus growths. It has also been recommended that dilute muriatic acid be used for the same purpose, but in my experience the addition of acids or similar extraneous materials, while they prevent the generation of fungus, increases the pain and tendency to inflammatory action at the seat of puncture.

H. AUGUSTUS WILSON, M. D.

331 SOUTH TWELFTH STREET, PHILADELPHIA.

A SOLUTION OF MORPHIA.

MR. EDITOR: If your correspondent "Querist" will add one minim of solution of carbolic acid (ninety per cent.) to each ounce of Magendie's solution his difficulty will be solved.

G. H. LYMAN.

A NOVEL METHOD OF TEACHING CLINICAL ANATOMY.

IN January last Dr. W. W. Keen of Philadelphia, Professor of Artistic Anatomy in the Pennsylvania Academy of the fine Arts, and one of the best lecturers on anatomy in America, delivered before the Anatomical and Surgical Society of Brooklyn, a strikingly interesting lecture On the Clinical Anatomy of the Lower Extremity and especially of the Knee and Ankle Joints. During the course of this lecture he suggested a novel method of teaching clinical anatomy, which not only deserves extended notice but might well be practically adopted in our medical schools.

After demonstrating a portion of his subject by means of casts and prepared bones, Dr. Keen said: "but turn from the cast of the dissection to our living model. Let him call the muscles of the knee into vigorous action, and then note here the high external vastus, there the lower and stouter internal, here the patella, and there the 'supra-patellar flat,' as artists call it, *i. e.*, the tendon chiefly of the rectus, and here the ligamentum patellæ, and then, if never before, you will appreciate not only the facts to which I have asked your attention, but also the value of this method of studying anatomy. A living interest is added which

the cadaver cannot give; muscles can be relaxed or contracted and their relations studied in relation to vessels, nerves, or other neighboring organs of importance; the lungs can be perceived in expansion and contraction; the position of the stomach, the liver, the intestines, the bladder, etc., can be shown; the course of the arteries exhibited; movable bones shown in various positions; the relation of parts in different postures shown clearly, and in their relations to medicine, surgery, obstetrics, etc., and all demonstrated at the time of most importance, *i. e.*, the very moment when they are being studied. I began this method of studying anatomy with my classes some twelve years ago, and from year to year have been more and more constantly impressed with its value. So true is this that I venture to affirm that *the living model should form as indispensable a part of the means of illustration in the anatomical lecture room as the cadaver.* In not a few respects, indeed, it is even more important. If its inconvenience and expense be urged, I may remind you that one model we always have, — ourselves, — and it is surprising how much anatomy we may learn from studying our own bodies."

The remainder of the lecture may be found in The Annals of Anatomy and Surgery for January, 1881.

SUDDEN DEATH IN DIPHTHERIA.

A PAPER on Sudden Death in Diphtheria and a discussion to which it gave rise at the Boston Society for Medical Improvement, were published in the JOURNAL for March 24th. As the subject is still fresh in the minds of our readers we print some extracts from a clinical lecture on diphtheria, by Dr. William Pepper, which appeared in the *Medical Gazette*, and a case of sudden death reported by Dr. Walsh.

DR. PEPPER'S LECTURE.

The patient, a healthy girl, six years of age, had a sharp attack of diphtheria about the 10th of last December. The membrane disappeared on the fifth, or sixth day, but recurred forty-eight hours later, and she was very much more ill than at first, with very extensive formation of pseudo-membrane. She was treated throughout both attacks with full doses of quinia, tincture ferri chloridi, chlorate of potassa, and solution of iron and chlorate of potassa was applied locally to the fauces. Again the membrane disappeared, as also the swelling of the cervical glands, and the subcutaneous infiltration, which had been extreme, slowly subsided; she regained strength and was apparently beginning to convalesce early in the third week of the attack, when she was seized with vomiting. The urine was slightly albuminous; no microscopic examination was made. The vomiting was constant, and resisted every effort of a most judicious kind for four days. On the 29th of December a consultation of the staff was held on the case and it was determined to stop all food by the mouth. The next day she seemed better, had vomited only once in the twenty-four hours, and had begun to retain a few drops at a time of milk and of lime water. On the 31st of December vomiting had entirely ceased; the child had retained teaspoonful doses of nourishment about every two hours; the injections had also been taken regularly and retained. The surface was pale and perhaps slightly cool, but this was not specially

¹ Read before Philadelphia County Medical Society, October 27, 1880. See Philadelphia Medical Times, January 1, 1881.

noticed; pulse small, but regular, 85-90 to the minute. There was no cough. The heart and lungs were examined and nothing unusual noticed. There was no valvular murmur, the sounds were faint, but neither tumultuous or confused. About twelve drops of tincture opii deodor. had been given in divided doses during the twenty-four hours. The amount of nourishment by the mouth was increased. Full doses of quinia were continued by the rectum. Two or three hours after the consultation it was noticed that the child's feet became cold, and that this soon extended to the knees and arms. The child's appearance changed; she gave a sudden gasping effort, made a motion, as though to push the mother away, and died without further struggle. At the post-mortem examination made on the following day, intense congestion of the liver was found, with enlargement and a deep purplish color. The kidneys were also deeply congested, the secreting cells of the tubules being in a state of "cloudy swelling." The spleen was slightly enlarged from engorgement. There was no pleural or pericardial effusion. The lungs were pale, retracted, and crepitant. The right cavities of the heart were enormously distended. The auricle contained much soft, dark, clotted blood. There was a firm white clot entangled in the tricuspid leaflets, and extending from there into the right ventricle, where it was very tightly attached to the muscular trabeculae by delicate prolongations; was thence prolonged into the pulmonary artery, the calibre of which was to a great extent obstructed by a firm, white, ante-mortem clot, which was moulded on to the leaflets and closely apposed to the walls. The left cavities of the heart contained less blood, but here also was a large firm ante-mortem clot, obstructing the mitral orifice, partly filling the left ventricle and prolonged into the aorta. The muscular fibres of the heart were in advanced fatty degeneration, their transverse striation being in places completely obliterated. The contents of the stomach were only ingesta. Its mucous membrane was for the most part not much congested, but at one spot near the middle of the greater curvature there was intense congestion. Otherwise the stomach was entirely normal. The occurrence of the heart clot is now known to be among the dangers in so many diseases that it demands careful study. It must be understood, of course, that I only refer to such clots as are formed in the heart some considerable time before death. It is well known that whenever the act of dying is protracted heart clots are apt to be formed. But such heart clots have little or no pathological significance. The true ante-mortem heart clot is distinguished by certain anatomical characters which are unusually well illustrated in these specimens. It is whitish, firm, and tough, it is apt to be moulded on the inequalities of the inner surface of the heart, and may be tightly attached by delicate prolongations passing around the muscular trabeculae. The tendency to heart clot in diphtheria is so very strong that it must never be forgotten or lost sight of. This accident may occur at any stage of the disease, and not rarely, as in this case, it takes place after convalescence seems to be established. I have also known it to occur at an earlier stage in cases which were apparently doing perfectly well. The only special determining influence which I have suspected in such cases has been an undue amount of muscular effort. This, therefore, should be scrupulously avoided in all cases of diphtheria, for this as well as for other reasons. Although usually followed by

death, it is important to be able to detect the occurrence of heart clot, if possible. The symptoms which may be stated as indicative of this condition are anxiety and great dyspnoea; pallor of face, and coolness of extremities; small, frequent pulse; and obscure, dull heart sounds with occasionally a blowing murmur. It will be seen that the symptoms in the present case were unusually obscure. I am inclined to regard the violent vomiting as one of the first results of the heart clot. The obstruction to the entrance of blood into the right cavities of the heart caused intense congestion of the liver and of the mucous membrane of the stomach. This would readily account for the obstinate vomiting, and careful examination of the stomach after death failed to reveal any other cause. It is true that there had been found, a few days before, a trace of albumen in the urine, and that the early stage of kidney disease, with cloudy swelling of the epithelium existed; but these do not suffice to account for the sudden occurrence of such violent and uncontrollable vomiting; without any symptoms of anaemia. Considering the marked ante-mortem characters of the clots, it must be admitted that they had existed for several days before death, yet, until a half hour before death, no symptoms arose to call special attention to the heart. It is true that they may have been masked by the frequent vomiting and the slight opiate effect which was maintained. There was no extreme dyspnoea, however, and the pulse was regular and not very rapid. There was also nothing special about the heart sounds, which were observed to be merely faint. It is important, therefore, to note how insidious may be the formation of heart clot and how closely we should be on our guard against it. When finally the clots attained such size as to seriously obstruct the orifices of the heart, and prevent the closure of the valves, very characteristic symptoms appeared, and were rapidly followed by death.

CASE OF SUDDEN DEATH IN DIPHTHERIA.

Dr. J. F. Walsh reports in the *Philadelphia Medical Times* the following case:—

July 1, 1880, called to see C. M., adult; she was suffering from a palmar abscess of diphtheritic origin; considerable general debility. The abscess treated with poultices, and opened July 3d. July 4th, general malaise, chilliness, headache, prostration, sore throat. Examination of throat revealed a diphtheritic patch on uvula; pharynx, half-arches, and soft palate very red and angry looking; tonsils enlarged, tumid, inflamed. Treatment: milk-punch, beef tea, etc.; tr. ferri chlor., gr. x., potass. chlorat., gr. v., every half hour, alternately; spray—thrown into the throat by means of an atomizer—of a mixture of acid carbol. m. xx. to liq. calcis f3 vj. every half hour. July 10th (two to three days after the first patch of exudation discovered) the whole throat was involved. Up to this date patient had been doing excellently; on this day the following conditions noted: throat devoid of exudation, returning to a healthy condition; tongue very slightly coated; pulse 60, full, but rather weak; respiration normal; slight mental confusion (but this has existed from the beginning of the sickness). Three to four hours after this last visit a messenger came in a great hurry, saying that patient had suddenly got much worse. On my arrival in the room she was dead. No violent symptoms preceded death. Husband says that she suddenly got ashy pale, and stopped breathing. No post mortem allowed.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 2, 1881.

Deaths reported 2923; 1058 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 635, consumption 428, lung diseases 401, diphtheria and croup 174, scarlet fever 114, cerebro-spinal meningitis 80, small-pox 59, typhoid fever 46, diarrhoeal diseases 43, malarial fevers 39, erysipelas 25, measles 24, whooping-cough 18, puerperal fever nine, typhus fever three, chicken-pox one. From *small-pox*, Philadelphia 41, New York 13, Chicago four, Cincinnati one. From *typhoid fever*, Philadelphia 10, New York nine, St. Louis four, Brooklyn, Chicago, and Lawrence three, Baltimore and Cincinnati two, Boston, Pittsburgh, Buffalo, Milwaukee, Charleston, Nashville, Lowell, New Bedford, Attleborough, and Clinton one. From *diarrhoeal diseases*, New York 14, Philadelphia five, St. Louis four, Chicago and Boston three, Brooklyn, Cincinnati, Milwaukee, New Haven, and New Bedford two, Pittsburgh, Charleston, North Adams, and Webster one. From *malarial fevers*, New York 14, New Orleans nine, St. Louis seven, Brooklyn five, Chicago two, Philadelphia and Baltimore one. From *erysipelas*, New York six, Brooklyn, Boston, Buffalo, and Providence three, Philadelphia and Baltimore two, St. Louis, Cincinnati, and Milwaukee one. From *measles*, New York nine, Baltimore and Nashville four, Boston two, St. Louis, Cincinnati, New Orleans, Chelsea, and North Adams one. From *whooping-cough*, New York seven, Philadelphia, Brooklyn, Chicago, Baltimore two, Providence, Lowell, and Westfield one. From *puerperal fever*, Boston three, Philadelphia two, Brooklyn, St. Louis, New Orleans, and Fall River one. From *typhus fever*, New York two, Brooklyn one. From *chicken-pox*, Charleston one. The mortality from cerebro-spinal meningitis has increased from 70 for the week ending March 26th to 80.

Two cases of small-pox were reported in Brooklyn and one in Pittsburgh; diphtheria 33, scarlet fever 22 in Boston; scarlet fever 17, diphtheria seven, in Milwaukee; measles 52, roseola eight, scarlatina 10, diphtheria nine, in Providence.

In 43 cities and towns of Massachusetts, with a population of

1,113,017 (population of the State 1,783,086), the total death-rate for the week was 20.71, against 22.20 and 20.19 for the previous two weeks.

For the week ending March 12th, in 149 German cities and towns, with an estimated population of 7,813,459, the death-rate was 27.4. Deaths reported 4113; 1954 under five: pulmonary consumption 579, acute diseases of the respiratory organs 455, croup and diphtheria 146, typhoid fever 63, whooping-cough 62, scarlet fever 55, measles and röteln 45, puerperal fever 34, small-pox (Königsberg three, Schweidnitz, Benthien two, Munich, Berlin, Aachen two) 10, typhus fever (Danzig, Elbing, Thorn, Posen, Berlin) five. The death-rates ranged from 13.8 in Wiesbaden to 40 in Augsburg; Königsberg 31.4; Breslau 35.6; Munich 29.4; Dresden 23.8; Berlin 24.5; Leipzig 19.5; Hamburg 25.7; Hanover 17; Bremen 27.8; Cologne 26.4; Frankfurt 17.1; Strasburg 30.9.

For the week ending March 19th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 20.6. Deaths reported 3001: acute diseases of the respiratory organs 345, whooping-cough 66, measles 56, scarlet fever 46, small-pox (London 13) 44, fever 41, diarrhoea 23, diphtheria 11. The death-rates ranged from 15.9 in Bradford to 26.5 in Wolverhampton; Birmingham 17.3; Leeds 18.2; Sheffield 20.2; London 20.5; Bristol 21.4; Manchester 23.8; Liverpool 25.4. In Edinburgh 19.4; Glasgow 25.3; Dublin 30.4.

In the 20 chief towns in Switzerland, for the weeks ending March 12th and March 19th, census population 548,301, there were respectively 41 and 51 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 16 and 18, diphtheria and croup 15 and six, typhoid fever 10 and 17, small pox one and six, whooping-cough four and none, scarlet fever three and one, measles two and three, puerperal fever one and none. The death-rate of Geneva 19, Zurich 29.1, Basle 32.6, Berne 24.6.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 2, 1881, TO APRIL 8, 1881.

MORFATT, P., captain and assistant surgeon. Relieved from duty at Camp Spokane, W. T., and ordered to Fort Walla Walla, W. T., until further orders, for medical treatment. S. O. 35, Department of Columbia, March 20, 1881.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, JANUARY 1, 1881, TO MARCH 31, 1881.

BAILLACHE, P. H., surgeon. Detailed as chairman, board of examiners, January 4, 1881. To proceed to Barnstable, Boston, and New Bedford, Mass., and Providence, R. I., as inspector, February 1, 1881. To proceed to Wilmington, N. C., as inspector, assume temporary charge of the service, and superintend the re-opening of the marine hospital at that port. March 12, 1881.

LONG, W. H., surgeon. Detailed as member, board of examiners. January 4, 1881.

FESSENDEN, C. S. D., surgeon. Detailed as chairman, board of survey, for the physical examination of officers of the revenue marine service. February 8, 1881.

DOLING, E. J., surgeon. Detailed as recorder, board of examiners. January 4, 1881.

GASSAWAY, J. M., passed assistant surgeon. Detailed as recorder, board of survey, for the physical examination of officers of the revenue marine service. February 8, 1881.

SMITH, HENRY, passed assistant surgeon. Granted leave of absence for thirty days from March 1, 1881, February 8, 1881. Upon expiration of leave of absence to proceed to Norfolk, Va., and assume charge of the service, relieving Surgeon R. D. Murray. March 15, 1881.

IRWIN, FAIRBAX, assistant surgeon. When relieved by Assistant Surgeon W. A. Wheeler, to proceed to Wilmington, N. C., and assume charge of the service, relieving Surgeon P. H. Baillache. March 30, 1881.

GUTHRIE, JOHN, assistant surgeon. To proceed to Key West, Fla., and assume charge of the service, relieving Passed Assistant Surgeon Smith. February 5, 1881.

WHEELER, W. A., assistant surgeon. To proceed to Charleston, S. C., and assume charge of the service, relieving Assistant Surgeon F. Irwin. March 30, 1881.

BENSON, J. A., assistant surgeon. To proceed to St. Louis, Mo., and report to Surgeon H. W. Saxatelle for duty. February 5, 1881.

CARMICHAEL, D. A., assistant surgeon. To proceed to Boston, Mass., and report to Surgeon J. Vansant for duty. February 5, 1881.

ARMSTRONG, S. T., assistant surgeon. To proceed to New Orleans, La., and report to Surgeon H. W. Austin for duty. February 5, 1881.

APPOINTMENTS. The following candidates having passed the examination required by the regulations were appointed as assistant surgeons February 4, 1881: DEWEAN A. CARMICHAEL, of New York, and SAMUEL F. ARMSTRONG, of Missouri.

A COMPETITIVE examination will be held in Washington, on the 25th of April, to fill three vacancies in the position of assistant surgeon in the United States Marine Hospital Service. Candidates must be between twenty-one and thirty years of age, and graduates of a regular medical college. Medical gentlemen desiring to apply for examination should make their applications to "Supervising Surgeon-General U. S. M. H. S., Washington, D. C.," without delay.

SO-CALLED CONCUSSION OF THE SPINAL CORD.¹

BY R. M. HODGES, M. D.

A CLASS of cases spoken of as "spine cases," or cases of "concussion of the spine," has, of late years, become notoriously common. These designations are used to signify the results of a traumatic violence inflicted upon the spinal column, unaccompanied by any external physical signs of local injury, but attended by the subsequent development of medullary disease, or of various functional disturbances, the assumed source of which is a lesion of the spinal cord.

The term "concussion of the spine" is, however, misapplied and erroneous. The bones of the spinal column may be stirred with vibrations from an inflicted blow, but the effect, so far as they are concerned, is a passing one. If they are transmitted to the spinal cord certain medullary symptoms or derangements may ensue. We may therefore properly speak of "the symptoms of or following concussion of the spinal cord," but the abbreviation, which usage has made familiar, is inaccurate, because it makes the cause of injury appear to be the injury itself.

The so-called "symptoms of concussion of the spinal cord" occur with great frequency after railroad collisions or accidents. Indeed, a distinct lesion of the spinal cord, consequent upon railroad collisions, has been asserted to exist; and the term "railway spine" is used in England as a popular epithet, synonymous with "concussion of the spine."

"The true 'railway spine,' caused by concussion, without any direct contusion, only takes place in collisions, and then only when the back of the injured person is turned in the direction from which the blow comes."²

"The force which carries a person forward in any sudden stoppage of a railroad train is represented as his own weight multiplied by the square of the velocity of the car he occupies."³

The provocation of these symptoms is not, however, the exclusive prerogative of railroad accidents. Defective highways, the non-removal of snow and ice from sidewalks, open and unguarded coal-holes and cellarways, the starting of horse-cars and omnibuses, etc., are among the familiar agencies by which they are said to be occasioned. Not rarely they succeed injuries, such as strains, twists, and wrenches, in which no jar or other force implied by the term concussion can have been exerted. Mere fright is declared to be a demonstrated cause, and the apparent inadequacy of the alleged source to which the symptoms are traced is often commented on. The suspicious attitude in which the subjects of them are frequently thought to stand is not diminished by the story of their origin.

It is sometimes remarked of an individual that he was "never himself again," after a certain "shock to his nervous system." A railroad train plunged into the chasm of an open draw-bridge, forty-six persons losing their lives, and some thirty others being more or less severely injured. One car broke in two near the middle, leaving its rear portion on the edge of the abyss, while the front went down. The occupant of the seat where the break occurred was suddenly confronted with the horrors of the scene, and the sight of his struggling and drowning fellow passengers. He received no bodily injury, but a long contest with nervous symptoms ensued, similar to those attributed to concussion of the spinal cord. He was obliged to give up active business, and to

the day of his death, many years afterwards, was unable to sit except upon an air-cushion, or to bear the jar of riding in any vehicle on wheels.

"During the bombardment of Strasbourg, many persons became paralyzed in consequence of the fright incident to the bursting of shells in their apartments. Most of them recovered, and could be classed as cases of emotional paralysis. Others became worse, and exhibited all the evidences of organic spinal disease."⁴

Sudden, entire loss of hearing, never recovered from, was once alleged to me to have been the result of a great fright in a storm at sea.

The variety of influences giving rise to the symptoms under discussion attests the inexactness of the name by which they are designated, and justifies the use of the words "so-called" as a prefix. The etiological importance attached to them, however, is due, not to the specific peculiarities of the agency by which they are provoked, but to the fact that annoying litigation and exorbitant claims for pecuniary damages are constantly the grave result of their existence.

Cases in which the so called symptoms of concussion of the spinal cord are developed present themselves under several forms, namely:—

(1.) Those which, at once, or very shortly after the injury, terminate in a fatal result.

(2.) Those which, followed immediately by a greater or less degree of paralysis, or other nervous derangement, terminate favorably, recovery taking place in a few days or weeks.

(3.) Those which are followed by serious and demonstrable evidence of increasing disease of the spinal cord.

(4.) Those in which the patient, at first apparently unaffected or but slightly harmed by the injury, within a variable period, often of considerable length, develops obscure general symptoms, referred to the spinal cord, which show little disposition to increase in severity, or to disappear, and are, in great part or wholly, subjective.

It is frequently asserted that symptoms of concussion of the spinal cord may be developed very long, even a year or more, after the accident. In the famous "Sagar case" two years and a quarter had elapsed.⁵ If so, they can be traced back by connecting links of definite, though perhaps slight, indications to an early period after the patient's injury. Oversight may explain the failure to detect them, but their appearance actually for the first time, after the lapse of months, should be looked upon with distrust, so far as connection with antecedent injury is concerned. It is the characteristic of concussion that its phenomena are immediate, though the recognition of them may not be equally prompt. Their aggravation into severe and dangerous symptoms of organic disease is not likely to be deferred for any very long period.

The first class of the above division is assumed to be one in which concussion of the cord has been inflicted, because after death no lesion is found, either with or without the aid of the microscope;⁶ the symptoms, so far as any may have existed, indicating an injury of the spinal marrow, which, without any autopsy, is not otherwise explainable.

The second class is familiar to hospital surgeons as the result of falls from "aloft," from stagings, ladders, roofs, or windows; burial beneath brick walls at fires, or banks of earth being excavated; and other accidents of a similar nature. The characteristic features which belong to it are that the symptoms are most severe at the onset, and that they speedily show a tendency to improve. It is often difficult to say in the beginning, or

⁶ Ziemssen, vol. xiii., p. 346.

for some time afterwards, that the lesion is not fracture of the vertebra, rupture of the medulla, or hemorrhagic pressure.¹ It is only when the rapidity of the recovery has begun to reveal itself, or where its completeness has been demonstrated, that, in the absence of evidence as to any other injury, a concussion of the spinal cord can be assumed to have occurred.

The third and fourth classes comprise the so-called "spine cases," familiar to lawyers and courts of law as well as to physicians. The third class embraces the cases which are known as myelitis, sclerosis, meningitis, etc., and are of comparatively rare occurrence from traumatic cause.² The fourth class includes those of functional disorder, presenting symptoms, the knowledge of which is obtained not by observation, but from the statements of patients, and which have no foundation in any recognizable medullary lesions; these being insufficient to cause fatal results, there are, consequently, no post-mortem examinations to enlighten us. Actual or anticipated litigation impresses them with exaggerated and emotional characteristics, and not infrequently provokes pure malingering.

The patient generally describes his symptoms somewhat as follows: Insensible, or greatly prostrated, or merely "out of sorts," for a certain length of time after the accident to which his ailments are attributed, evidence of settled injury gradually subsides, and he believes himself to have recovered. Such may be actually the case. But it often happens that he shortly becomes indisposed again, and unable to pursue his business with his habitual energy. He loses flesh; grows haggard and "changed;" complains of pains in his back, head, and elsewhere, and of a confused mind and failing memory. His sleep is disturbed; he has a feeble circulation; becomes irritable in temper; exhausted by slight efforts, mental or physical; tired by conversation; unable to walk without extreme fatigue; depressed in spirits; confined to the house, and finally even to the sofa. A tenderness up and down the spinous processes of the vertebra; functional disturbance of the bladder and sexual organs are or may be present; and impairment or complete abolition of one or more of the special senses, and a certain degree of paresis, are often asserted to exist. The mental condition sometimes verges on imbecility or insanity. The digestive organs are but little, if at all, disturbed.

A certain number of cases of inflammation or degeneration of the spinal cord, following concussion, find their way into the courts; but they are rare in this connection compared with those whose claims have no similar or equivalent foundation. They present many difficulties of diagnosis, not so much with reference to their general character as in regard to certain details and refinements; and in these particulars they tax the skill of the most distinguished special pathologists. While they often present exaggerations, due to collateral surroundings, their objective symptoms are not readily confounded with the vague phenomena of the constantly recurring cases, which owe their seriousness to the peculiar circumstances of a money-making nature by which they are invested.

To this latter class the following pages are devoted, their object being to call attention to the characteristic peculiarities which follow an assumed concussion of the spinal cord when the added element alluded to is present, or which are begotten by it when no real organic lesion justifies their development.

Whenever the reality, nature, extent, and future of an alleged injury, such as is under consideration, becomes the subject of legal inquiry, extreme views and antagonistic statements are sure to be advanced. The patient's own medical adviser is sometimes in the wrong. His personal relations and familiarity with the individual himself are apt to encourage an acquiescence in statements which a stranger would not hesitate to challenge. On the other hand, the injustice of overlooking genuine signs of organic lesion may, and perhaps often does, occur, from prejudice or ignorance on the part of a real or so-called expert, or because the subjective symptoms deceive him. Where both classes of symptoms are present, the objective should, and usually do, predominate, leaving little, if any, doubt in the mind of a candid observer as to their existence or significance.

The patient himself, who has instituted, or is on the point of instituting, a suit for damages, stands in a very different position as regards a liability to exaggerate from one who has no motive for deception. In mild as well as in severe and serious cases such persons, with perfect honesty of conviction, believe themselves the subjects of every symptom which conversation or cross-questioning suggest.³ A designing person may simulate a type of disease which neither exists nor has existed, or a truthful individual may overstate his account of symptoms really due to the cause assigned, but which by no means possess the seriousness attributed to them, or he may ascribe to a particular injury ailments which it has in no way occasioned. Judges of courts do not hesitate to express their opinion of the extravagant, if not dishonest, nature of a large number of the suits in which the plea of "concussion of the spine" is maintained, or, with increasing frequency, to set aside the verdicts of juries by whom they are tried as excessive or contrary to the weight of evidence.

For quite manifest reasons the simulation of disease affecting the nervous system appears to be especially chosen by impostors. In the old days of the press-gang, insanity, epilepsy, and paralysis were frequently assumed by the victims who desired to escape military service. Malingers and hysterical impostors in modern times have also successfully counterfeited various forms of spinal disease. An account of "the most extraordinary case of malingering on record," which was successfully carried out in eleven different hospitals, many eminent physicians and surgeons being deceived, by a man who, for four years, between 1868 and 1872, passed his time in various London hospitals, simulating certain nervous affections, will be found in the *Lancet*, vol. i, 1872, p. 219.

In a case not long since tried in this city (Hackett v. The Eastern R. R. Co.) the plaintiff claimed to have been injured in the spine and to be paralyzed. The jury awarded him \$39,500. This verdict was set aside as excessive, but the court determined that if the plaintiff consented to a judgment of \$30,000 a new trial would not be ordered. The case was finally settled out of court for \$20,500, a little more than half the award of the jury, the plaintiff preferring to accept that sum rather than to take the chance of a larger though uncertain amount, the payment of which would be deferred by a new trial or the arguments on exceptions taken at the first.

Of twenty-one cases where the so-called symptoms of concussion of the spinal cord were alleged to be present which have been under my personal care, ten are believed have been proved deceptions, and in six the diagnosis,

¹ American Journal of Medical Sciences, U. S. Vol. XV, p. 74. Achurst, Injuries of the Spine, page 9. St. Bartholomew Hospital Rep., 1869, page 15. *Lancet*, January 8, 1876. Rev. medical, vol. iv, p. 649.

² Transactions of the London Pathological Society, vol. X, p. 29. *Lancet*, December 13, 1876. *Medical Times and Gazette*, Vol. I, p. 475. Transactions of the London Pathological Society, vol. viii, p. 41. *Archiv für Psychiatrie*, etc., 1878. *Oesterreich. Jahrbücher*, III. 4 Heft, Wien, 1879.

³ *Lancet*, January 15, 1881, page 101.

as regarded deception, was doubtful. Of twenty-eight similar cases observed by Rigler,¹ seven were found to be simulated, and in thirteen the diagnosis in regard to fraud was doubtful. Of forty-nine cases, therefore, it would appear that thirty-six, or three fourths of the whole number, were really or probably deceptions.

This instinctive or inherent tendency to exaggerate being so generally acknowledged, it follows that in estimating the indications of any given case the first endeavor should be to eliminate the equivocal manifestations which are or may be due to a desire not to get well, to an over-eagerness for heavy damages, hypochondriasis, natural mental weakness, general bodily feebleness, and malnutrition. Rheumatism, rheumatic arthritis, uterine disease, the secret and subtle influences of syphilis,² and chronic renal disease, — both of them active and important factors in the production of disorders connected with the nervous centres — are also to be carefully considered in any attempt to discriminate between traumatic and pathological conditions. No one who remembers "spinal irritation," formerly of frequent occurrence, but which "has almost passed from the memory of the present generation of physicians" (Ziemssen) can fail to recall its indefinite features, similar to those following "concussion of the spine," and not be impressed by the reminiscence with the number of symptoms which may be viewed with suspicion as having no necessary connection with antecedent injury.

The so-called symptoms of concussion of the spinal cord are liable to be unnecessarily prolonged in other countries than our own. Rigler gives the name of siderodromophobia to a particular phase of nervous irritability exhibited by railroad employees, the result of prolonged service and exposure to constant jar, which is liable to be exacerbated by traumatic influences in a very active and disturbing manner, especially in those who have shown any predisposition to its existence. He describes it as a spinal irritation, more or less intense, with a general disposition to hysteria, and a morbid aversion to the habitual occupation. Before the law of 1871, by which the German railroads became liable for injury to their workmen as well as their passengers, employees thus affected, being anxious to gain their living and to keep at work, managed by an energetic effort of the will to control their nervous condition. He attributes the increased number of injured employees since 1871 to the absence of any further motive for this endeavor. The number of accidents which were the subject of claims in the five years, 1871-76, was, on one road at least, nine times greater than before the new law, and the sums claimed were much larger. In fifteen derailments before 1871 there were but two injuries leading to claims for disabilities incurred. Seven derailments subsequent to 1871, occasioned eighteen suits at law.³

I have met with what I suppose to be siderodromophobia but once. In this case an engineer of superb physique, and twenty-six years' experience in his vocation, although thrown from his locomotive into an adjoining ditch by a collision, was so little hurt that he immediately set to work drawing the fire from under his boiler. The hysteric condition above described developed itself almost at once, and after the lapse of more than two years he still had such a dread of his occupation that he was practically disqualified for its continuance.

In by far the larger proportion of litigation cases, where so-called symptoms of concussion of the spinal cord are alleged to exist, purely subjective phenomena are the predominant features. If the nervous centres are really involved the changes in most instances are secondary, and result from anemia and malnutrition, developed by circumstances only indirectly connected with a traumatic cause, such, for example, as are due to poverty, demoralizing mental influences, particularly

those peculiar to the female sex, or which arise from indignation at the cause of the injury received, loss of employment and wages, anxiety on account of responsibilities left unguarded, or the accumulating indebtedness being incurred.

Certain uniform and prominent points connected with cases in which claims for compensation are set up call for special comment.

Sprains of the ligaments of the vertebrae, rupture of the complicated aponeuroses and muscles of the back are common and enduring lesions, too obvious in their symptoms to need detailed description. They are, without exception, the most frequent cause of the phenomena assumed to be those following concussion of the spinal cord. They give rise to much local pain, to a rigidity of the spine, a difficulty in rising from the seat, a stiffness in walking, and contribute readily to any disposition on the patient's part to make much of his injury. The attitude, or the cautious and constrained movements of the body, may be made to suggest inferences which cannot be too guardedly accepted.

The tenderness to touch, as well as the intermitting pain characterizing periosteal inflammation of the vertebrae, which occasionally follows blows on the spine, often leads to the impression, on the part of patients at least, that they are symptoms of so-called concussion of the spinal cord.

In three cases that have come under my observation the thickening of the bones which attended the above-named condition was made much of by the counsel for the plaintiff. In one, occasioned by the fall of a snow-slide on the back of the neck, great deformity and discomfort resulted from the increased growth in the cervical and dorsal vertebrae. In all recovery took place, so far as pain and general symptoms were concerned, though the osseous hypertrophy remained permanent. Mr. Birckett has, however, reported a case in which the exudation reached such a degree as to occasion paraplegia from pressure on the cord, leading finally to a fatal result.⁴

Neuralgic and hysterical phenomena, due to injury of the coccyx or sacrum, from falls or blows, and resembling in some degree those attributed to concussion, are by no means uncommon.⁵ The ligaments of the pelvis, which help to form foramina for the passage of important nerves, may be more or less damaged in the manner just alluded to, and the abiding pain (if not the nervous manifestations), which attends the injury, is precisely that which follows ligamentous sprain elsewhere. Deep-seated pelvic inflammation, and uterine displacement, give rise to painful sitting and walking, accompanied by neuralgic sensations and hysterical symptoms.⁶

In all cases where concussion is said to have been inflicted, pain on pressure over the spines of the vertebrae is adduced as almost conclusive evidence of its results. It is, however, very questionable proof of a lesion connected with the spinal cord. Pressure on these processes, especially on those of the upper dorsal vertebrae, produces pain and other symptoms in persons who present no signs of medullary disease.⁷ "It is probably no exaggeration to say that of one hundred patients who complain of spinal pain, in ninety-nine there is no spinal disease."⁸

Derangements of sensation are so decidedly subjective

⁴ *Lancet*, vol. ii., 1868, p. 763.

⁵ Periostitis of the coccyx is not an infrequent result of a direct blow. I have twice had occasion to remove this bone for subsequent necrosis.

¹ *Rév. médicale*, No. 29, January, 1879, p. 249.

² "Seventy-five per cent. of all cases of locomotor ataxia are of syphilitic origin." (*Gowers*, *Medical Times and Gazette*, October 16, 1880.)

³ *Rév. Méd.*, Jan. 1879, page 249.

symptoms, perceptible to the patient alone, that they must always be accepted with hesitation, especially when described under the terms of "burning," "flashes of pain," "formication," etc. "Modified sensitiveness to touch is inexactly appreciated by compasses or the aesthesiometer; the individual variations, and those of the same parts on the two sides of the body ("tactile squint," as it has been called), often depriving these instruments of any positive value.

Derangements of motility, as shown in a complete or partial loss of muscular power or control, are readily simulated, and can be accurately estimated only by the aid of electricity, by etherization, and by the presence or absence, in a greater or less degree, of the various reflexes.

Unfortunately, the tests of electricity, the experimentum crucis of etherization, and various physical explorations, are often refused when they are proposed. Indeed, the privilege of any medical examination is sometimes denied the defendant, and justice is deprived of evidence which, in certain instances, can alone distinguish real from unreal symptoms in a conclusive manner.

In 1872 the Metropolitan Railroad was mulcted in the sum of \$10,000 by a man, the detailed account of whose symptoms satisfied the jury that, as the result of a concussion of his spinal cord, he was utterly enfeebled in body, and wholly unable to earn his living, or to perform the ordinary acts of life with comfort. It required the united strength of three policemen to take him to the station-house, when, at the close of the trial, he celebrated his victory by getting too uproariously drunk. He has ever since followed the active and laborious calling of a junk dealer. Etherization, in this instance, would, undoubtedly, have shown the injustice of the man's claim.

The inspectors of the state prison at Charlestown asked me, some years ago, to see an apparently paralyzed convict, whom they suspected of malingering for the sake of escaping hard labor and of getting the better food given as hospital diet. He had been in the prison hospital for a year, and, in fact, was about being "pardonned out" on account of his incurable condition. Suspicion had led to his being closely watched; but no one had ever seen him move his lower extremities, which were said to be paralyzed to such a degree that he could neither get out of bed nor turn over. No pricking, pinching, or tickling, or any other familiar test, could elicit the least sign of motion or sensation. His food, at one time, was placed so far out of his reach as to oblige him to get out of bed if the pangs of hunger compelled him to seek it. This experiment was persisted in so long that the man was nearly starved, his food remaining untouched; and the inspectors finally put an end to a procedure which seemed to them too cruel. The test of ether was then proposed and tried. Not a limb stirred during its administration; but after it had been pushed to complete anesthesia he was allowed partially to come out from its influence. He then got down from the table on which he had been lying, walked and danced about in his semi-conscious state, desired to fight the bystanders, and, later in the day, was given his choice between solitary confinement and going to work.

Assertions are common in regard to frequent micturition and incontinence of urine. Without exploration of the urethra and bladder statements in regard to disturbances so capable of simulation can have little value as indications of injury. No single symptom is more frequently and emphatically advanced than the alleged existence of sexual impotence, or "loss of power." The actual fact is obviously incapable of verification.

In an instance where a claim of impotence was strenuously put before the jury, and their sympathy given expression to in a verdict of \$18,000, the plaintiff was convicted of bastardy not long after the trial.

In another case, where the claim was settled for \$10,000, this alleged disability being the chief ground for damages, the claimant was married a year afterwards, and his wife in due time gave birth to a child, presumably legitimate. Fifteen months after the Wollaston accident a similar event occurred in the family of one of the injured on that occasion, who claimed to have been made wholly impotent, and was paid \$5,500.

Physiologists have given much study to the nerves controlling the genital organs, bladder, and rectum. The functions of the genital organs "depend on the integrity of the reflex loop to and from a special centre situated in the lumbar enlargement. Disease of this centre, or of nerves leading up to or from it, abolishes sexual action. If the disease is higher up this centre participates in the overaction of the reflex functions. It is, however, one of the superficial reflexes, the excitation being from the skin, and it shares the excess of the superficial rather than the deep reflexes, being especially intense when the conduction of sensation is impaired. Sexual power, however, is affected, even in these cases, on account of the fact that *psychical influences* are an essential for the due action of the centre."¹ It would seem, therefore, that the symptom of impotence may be a functional one; that it does not necessarily imply an organic lesion, or permanency of existence, and that its importance as bearing on the question of damages has been overestimated.

The special senses of sight and hearing cannot be lost or impaired without ready recognition.² By tests well known to ophthalmology and otology attempts at simulation can readily be detected. Patients often assert that they are unable to read, but the disability generally depends upon other causes than actual impairment of vision. With regard to the sense of taste and smell there are no means at present known by which deception can be recognized. In one instance where both of these senses were annihilated by concussion, and responded to no tests which ingenuity could devise,³ although twelve years afterwards, by the report of the patient's husband, the general health was regained, they still remained impaired. At the time of trial, and when evidence in regard to the point was put in, there were those who did not believe that they were so completely lost as was asserted to be the case. In a case of chronic myelitis from railroad injury, which occurred in 1872, absence of the sense of taste has never been restored.

At the Medical Society of London, March 7, 1881, "Mr. Wordsworth read a paper on the Defects of Vision attributed to Railway Collisions, speaking only of those cases in which no structural lesions can be discovered, of which he had seen about twelve who complained of dimness of vision, etc., and inability to apply themselves continuously to any occupation requiring the use of their eyes. On examination no signs of injury beyond slight hyperæmia of the fundus oculi were discovered. Yet in all the cases they received considerable pecuniary compensation for the injuries, on account of the unfavorable prognosis that had been given. He had ventured to give a more cheerful opinion as to the ultimate recovery, and, so far as he had been able to trace the cases since, he believed they all recovered on the settlement of their claims, and had resumed their wonted occupation. He remarked on the fact that medical men were seldom consulted in these cases, except with a view to their assisting to obtain compensation; stated that in a long experience in hospital and private practice he had never seen any of these cases simply as a patient either before or after the settlement of their claim for compensation. These are circumstances which give rise to a doubt whether they are really *bona fide* cases, and are entitled to the importance that has hitherto been attached to

¹ Gowers, Med. Times and Gaz., December 13, 1879.

² The eye in its relation to spinal injuries is discussed in the Archives Gen. de Med., 1869, vol. ii, p. 236; the Lancet, January 15, 1870, page 76, and British Med. Jour., July 2, 1869.

³ Quinine, salt, red pepper, aloes, assafoetida were put on the tongue and swallowed without any apparent impression being made. Fine cut tobacco mixed with sugar was chewed as an agreeable morsel. Valerianate of ammonia, ether, and a most villainous stuff known as "Hartford cicuta" were snuffed up without any apparent perception of odor.

them. The cases referred to by him manifested no retinal changes."¹

The apparently trilling but continuous jar to which traveling railroad officials are subjected is declared sufficient in itself to provoke nervous disease, "characterized by a loss of visual power, and of hearing, and a sensation of feebleness and numbness which renders the acts of walking and standing painful. Persons affected grow thin; the generative power dies out; the body is agitated by starting and convulsions, and the intelligence is weakened." One fifteenth of the drivers and firemen of the Lyons and Paris Railroad, in 1857, were found to be suffering from affections of the brain and nervous system.² I am informed by one of the most experienced railroad superintendents in New England, that in his opinion, this statement would apply with equal truth to engineers and conductors in this country.

If constant traveling by railroad engenders a morbid predisposition to disease, the motto *periculum privatum, publica utilitas*, which George Stevenson inscribed on the first car, drawn by the first engine, along the first railroad track, would not inaptly adorn the panels of those which nowadays carry many a half-invalid, middle-aged, and over-worked professional or business man, fifty or more miles a day, from a house in the country, or at the seaside, to his office or counting-room. The wear and tear of engrossing affairs; the high-pressure work of a day which is shortened to the interval between morning and evening trains; the strain of the hurry and running to reach the station, aggravate the pernicious jar of habitual travel, by which railroad men are, as they say, "torn to pieces," and reveal their combined effects in the "nervous exhaustion" so often experienced by the class of persons alluded to, and constitute a circumstance, not without importance, in connection with many cases where the injuries of a collision, or other accident become the subject of litigation.

The opinion is sometimes expressed in evidence for the defense given before juries that the injury was inflicted at a point so low down in the back that the spinal cord cannot have been hurt; that the cauda equina is alone involved, and consequently that symptoms such as might occur if the cord itself were implicated do not exist in reality, or must be otherwise explained.³ No more erroneous statement could be made. The severest form of myelitis as well as the subjective symptoms of concussion of the spinal cord may follow such an injury. A case reported by Mr. Curling⁴ is in point. A fall on the nates while sliding, which did not prevent the boy from getting home unaided, was followed in five days by paralysis of the lower extremities, subsequently by loss of reflex action, retention of urine, bed sores, etc., and finally by a fatal result. At the autopsy no injury of the spinal column was found, but the cord was softened and the seat of universal pathological changes. Here there was no motive for deception and the symptoms followed the course of a recognized disease. In a case, however, reported by Dr. S. Cabot, where a woman fell on the floor in a sitting posture, a child having pulled away the chair in which she was about to place herself, no part of the spine being struck, insensibility and con-

vulsions occurred at once, followed by blindness, deafness, and loss of the sense of smell.⁵ These anomalous, if not hysterical symptoms, together with others assumed to be those of concussion of the spinal cord, made the subject of them a permanent pensioner on the bounty of the family with whom she lived. In the estimation of those who knew her, complete restoration eventually took place.

(To be concluded.)

FOREIGN BODIES IN THE BLADDER.⁶

BY ARNER POST, M. D.

THE little specimen I have to show to-night as a basis of this paper is a lead pencil about three inches long, covered with urinary salts. Its history is as follows: The patient, while at sea, fell from aloft, striking astride of some object on deck, bruising his perineum, but not otherwise injuring himself. This contusion was followed by retention of urine. The ship's medicine chest not being furnished with either a catheter or a bougie, with a sailor's ingenuity he constructed an instrument by fastening a lead pencil to the end of a wire. The lead pencil had the additional portion, which is glued on to retain the lead, removed. When the instrument was passed into the bladder the urine escaped by its side. Catheterization was successfully performed three or four times, but at the succeeding attempt the pencil separated from the wire and slipped into the bladder. There it remained about three months without causing much inconvenience. At the end of that time, being then ashore, he was seized with retention. Consulting an apothecary in whose skill in urinary difficulties he had reason to have confidence, he was given a diuretic, with instructions to hold his water as long as possible, then to pass it suddenly with all his force. Following directions, he failed to pass his water, and came into my hands in the anxious condition common to patients with retention, with the end of the pencil just visible within the meatus. He was immediately etherized, and the pencil extracted (not without the application of considerable force) by means of a pair of dressing forceps. Well-marked cystitis was present, but the patient almost immediately passed out of my care, and his subsequent history is unknown. There was nothing to particularly awaken suspicion at the time, and his story was accepted as probably true, the not uncommon use among sailors of bougies of their own manufacture giving an additional air of probability to the account. At present I should be a little less ready to accept a similar history, and be more inclined to believe this might have been one of the very numerous cases in which a foreign body is passed into the bladder from other motives than the very legitimate one of relieving strangury.

The possession of this little specimen has interested me in the various accounts of foreign bodies in the bladder, and led me to give a short *résumé* of such cases as seemed of more than usual interest. This paper has no other value than the slight interest attaching to a superficial history of unusual cases.

Foreign bodies in the bladder (calculi not being under consideration) may be classed under the following heads:—

¹ Lancet, March 19, 1881, page 462.

² Lancet, Jan. 18, 1862, page 80.

³ The spinal cord terminates and the cauda equina begins at the lower border of the first lumbar vertebra. They occupy respectively three fourths and one fourth of the spinal canal.

⁴ Transactions of the London Pathological Society, vol. viii., p. 31.

⁵ Boston Med. & Surg. Journal, Feb. 5, 1880, p. 132.

⁶ Read before the Boston Society for Medical Improvement, April 12, 1881.

(1.) Portions of instruments introduced by surgeons and accidentally broken off.

(2.) Articles not ordinarily classed as surgical instruments, but introduced by patients for legitimate purposes.

(3.) Articles introduced accidentally in some other way than through the urethra.

(4.) Articles introduced for other than legitimate purposes.

A very large proportion of foreign bodies in the bladder consists of portions of urinary instruments which have broken while in use or have accidentally slipped from the surgeon's hands. Certain instruments are particularly liable to break, as gutta-percha bougies, which grow brittle with age, and fortunately are now seldom used. The elm-bark bougies, which are said to have been very common at one time in the South, were specially liable to fracture. In the earlier days of lithotomy it was not very unusual for the lithotrite to separate, and Lallemand's *porte-cau-fique* has often left the cup behind. Cases in which the whole or parts of instruments have slipped into the bladder are known to every surgeon of large experience; they occasionally appear in every hospital, and the specimens adorn every well-furnished museum. Of such ordinary cases it is unnecessary to make further mention.

One of the most curious cases in this category was a calculus removed by Sir Astley Cooper, which had formed around a female catheter which had lain for months in a woman's bladder. The instrument had escaped from the surgeon's hands into the urethra, and fearing to meet the responsibility of the accident he said nothing about it, but allowed it to remain. The affair was unknown until the extraction of the stone by Sir Astley.

Patients are often led by necessity or a desire for economy to substitute, for instruments regularly made, articles of domestic manufacture. Wooden bougies were not unfrequently exhibited by patients at the marine hospital during my residence there, and a similar instrument is mentioned incidentally in a case of cystitis reported some years since by Dr. Arthur Cabot as occurring in the practice of his father. I have so far hit upon no accident from the breaking of such an instrument, though several pieces of wood have been found in the bladder. I have no doubt some of them were introduced in this way.

The accidents that befall these extemporized instruments cause strange revelations of domestic economy, and are of particular interest in connection with this specimen, which would probably be classed under this head. From among the many curious cases of this character the following may be taken as samples:—

Sir Astley Cooper tells a case occurring in the practice of a provincial surgeon as follows: A man had had difficulty in passing water for two or three years, and for many months before his death had been in the habit of relieving his bladder by introducing a piece of straw. He became quite expert in the use of this instrument. One day, however, he unfortunately let the straw slip, or it broke off, and from this day he became worse. Notwithstanding his sufferings, he never made known the real cause of them, and the matter was revealed only by the post mortem; further details were then given by the wife. There were found in his bladder, behind an enormous prostate, several calculi, with bits of straw for a nucleus, three such concretions being formed at intervals along a single straw.

In the *New York Medical Gazette* for 1852 is an account of an attempt to use a piece of sealing-wax as an instrument for dilation. An old gentleman, the Hon. Mr. H., had been troubled for some years with difficulty in urinating. Various medicines giving no relief, he resorted to the mechanical assistance of a piece of sealing-wax three eighths of an inch in circumference. Of this bougie he left a portion two and one half inches long in the urethra; to remove this the gentleman had recourse to a wire, and pushed the sealing-wax on into the bladder. There it was made the subject of various experiments in regard to the solvent action of chloroform, which were successful in causing it to adhere to the walls of the bladder, whence it was finally removed by lithotomy, many small portions adhering so firmly as to necessitate their being left to separate by themselves.

In Guy's Hospital Report for 1837 is figured a calculus formed about a piece of the stem of an ordinary clay pipe, which had been used as a bougie by a man while intoxicated.

An important case in the history of surgery is given in the *Medico-Chirurgical Transactions* for 1807. Mr. Thomas, in whose practice it occurred, related the case substantially as follows: A lady was seized with retention of urine, and her husband, "who had read much in surgical books," undertook to relieve her; for this purpose he used an ivory ear-pick, and was successful in causing the urine to flow. The stream, however, was not satisfactory to him, and he re-introduced the ear-pick, which slipped from his fingers into the bladder. This gentleman's reading had given him a very well-grounded horror of incision of the urethra, and he declined the operation when proposed by the surgeon; Mr. Thomas accordingly dilated the urethra with sponge tents, and succeeded in removing the extemporized bougie.

Mr. Thomas did not claim originality in this matter. It had been previously proposed, at least. A case had also been reported by Mr. Broomfield, where he had effected dilatation in a young girl by introducing the caecum of a small animal in a collapsed state into the bladder and filling it afterwards with water.

[Incidentally, it is worthy of mention that at the close of the same article Mr. Thomas gave an account of the introduction of his whole hand into the rectum in pursuit of a stick which a young man had passed in to bring about an evacuation.]

This case of Mr. Thomas's had very important results. In 1817 Sir Astley Cooper published a paper in which he said he had resolved to employ Mr. Thomas's principle on the first opportunity, and having used it successfully and told his cases in his lectures, two others had been communicated to him by former pupils. The use of the sponge was not only painful, but very disagreeable, as the woman was usually obliged to retain her urine while the tent remained in place, which must have been almost impossible in bladders rendered irritable by the presence of a foreign body. To meet this difficulty Sir Astley first proposed a groove by the side of the sponge or a catheter through the middle. It finally occurred to him that the dilatation might be mechanically done by an instrument which would allow the escape of the urine. He acted on this idea, and in 1822 read a paper on the removal of a stone and a piece of catheter by a dilator made for him by Mr. Weiss, who, as Sir Astley says, "with his accustomed ingenuity immediately suggested an instrument infinitely better devised

than any I could have contrived for the purpose." In his first case the dilator was retained in place from eight A. M. to four P. M., when the finger could be introduced. The patient never lost the power of retaining her urine.

From the ease of dilation Sir Astley determined to do the operation in minutes instead of hours, and gave the history of his second case: A patient, occasionally subject to retention, had acquired the art of catheterizing herself; on one occasion the catheter broke, and a part remained in the bladder. The dilator was introduced, and in two minutes the urethra was sufficiently dilated to allow the introduction of a finger. Her urine passed involuntarily until the next menstrual period, after which she gained control of it.

The same article contains in an appendix an account of a case by Thomas Chapman, of Wandsworth, in which a female catheter slipped into the bladder while the operator left the bedside to reach a basin from a table. The extraction was accomplished by digital dilatation, forceps, little finger, and forefinger being successively introduced, without patient or anybody else being aware of the accident or the means taken for the recovery of the instrument.

Such are some of the steps which have led up to the now not unusual operation of rapid dilatation of the female urethra. Sir Astley Cooper's lead was not steadily followed, however, and his connection with the operation has for the most part been forgotten.

The annals of military surgery contain numerous cases in which shot-wounds of the bladder were complicated by the presence of foreign bodies in the viscus. These bodies may be either the projectile or fragments of bone, bits of clothing, or splinters of wood. Sometimes these bodies, if small, may be evacuated through the urethra. More often they form the nucleus of a calculus, which can be removed only by surgical interference. During the war of the Peninsula a sailor was struck by a ball which penetrated the right ilium. After suffering from retention for five days he passed per urethram a roll of shirting and trousers material, two inches in length. A month later lithotomy was done by the elder Cline, and a flattened ball with a piece of bone adhering to it, and encrusted with urinary salts, was removed.

One of the specimens of the Army Medical Museum is a calculus formed about an arrow-head, removed from the body of an Indian.

The cabinet of this society contains a large phosphatic calculus which formed about a conical musket-ball. The man was shot through the sacrum at Gettysburg, and the calculus was removed by lithotomy, in 1871, by Dr. Cabot.

The medical history of the war gives a table of twenty-one cases of lithotomy for the removal of traumatic vesical calculi, with extended accounts of several cases, and exceedingly interesting notes from a very wide field.

In several cases pins have been found in the bladders of children a few months old, which had apparently penetrated either from the rectum or by some other indirect passage, and parasites of various kinds have gained admission, and been passed per urethram.

In Eve's Remarkable Cases is the story of a young woman who passed from her urethra, one week before the birth of an illegitimate child, a hair-pin, which she

claimed to have swallowed two years before. She produced three witnesses who were in the room when the hair pin had gone down her throat.

The catalogue of substances introduced for other than legitimate purposes is a very long and curious one. Pieces of French chalk, barometer tubes, a watch chain, stilettos, pins, hair-pins, hair, feathers, pencil cases, pen holders, matches, an ivory whistle, small keys, a mustard-spoon handle, a leather boot lace, grass heads, and a portion of a suspender buckle.

It is but charitable to suppose that some of the individuals who thus abused their urethra were insane, as was certainly the case with the patient at the McLean Asylum who introduced the portion of the suspender buckle, which is now preserved in the museum of this society.

The most prominent position in this list must be given to the hair-pin; as a foreign body in the bladder it knows no limits of age, sex, or nationality. Its occurrence in that situation is almost too common to need more than mention, though the difficulty of extraction will always make it a subject of interest.

Dr. Bigelow reported a case, some years ago, where a girl repeatedly introduced both hair-pins and common pins.

Of the other cases some few are worth giving in detail. In the *Lancet* for August 23, 1873, is reported the case of a woman who on admission to hospital complained of intense pain in the abdomen. The urethra, which was abnormally dilated, easily admitted the introduction of a finger into the bladder where there was felt a hard voluminous body, evidently the cause of the pain. The woman then mentioned that on account of great difficulty in making water she had passed a candle through the urethra and had let it fall accidentally into the bladder; forceps were easily passed through the canal, and after some efforts the candle was caught by the wick and drawn out. The end of the candle, which had been rounded with a knife, was seen to be covered with calcareous matter.

The reasons assigned for the introduction are often as singular as the articles introduced. Mr. Beckett, in Holmes's System of Surgery, tells the case of a man who introduced the wooden handle of a steel penholder with the intention of stirring up some sediment which he believed to be there. It was necessary to open the urethra for its removal.

One of the most ludicrous cases was that of a man who introduced a piece of French chalk of convenient size and shape to the middle of which was attached a piece of string, to the other end was tied a piece of an ordinary shoe-horn. The man actually entered Gay's Hospital with this dangling from his penis.

Patients are sometimes made the subject of experiments by others. Mr. Harrison, of Liverpool, tells the story of a militiaman who was thus made the subject of a practical joke; while under the influence of liquor a prostitute, in whose company he was, introduced up his urethra a pencil case about four inches long, which Mr. Harrison was fortunate enough to remove the next day.

In 1851 Dr. Mackenzie, of Edinburgh, removed five calculi from the bladder of a laborer which were remarkable for their uniform size and shape. They were found to contain ordinary field beans as nuclei. Six months previous, while intoxicated, he had quarreled with two companions who had knocked him down and, while he was insensible from the combined effects of

liquor and the blow, had crowded beans into his urethra, as well as into his mouth and his rectum.

In 1853 Dr. Van Buren removed a stone formed upon a piece of slate pencil which the young man claimed had been slipped into his urethra by a boy with whom he was in the habit of playing.

When I was first told of the directions given by the apothecary to my patient I was inclined to look upon it as the advice of a man, unable to carry out further treatment, more desirous of receiving a fee than of returning a proper equivalent (as without doubt it was), and the result as a happy accident; but the number of cases in which similar means have been followed by an equally fortunate result would seem to show that it is not an altogether irrational procedure. A most extraordinary result of this kind is given in the *Philadelphia Medical Times* for 1872. Dr. W. Hunt reports a case of a boy who passed a galvanized watch chain down his urethra. The watch chain, which had a string attached to the middle, slipped into the bladder; in pulling upon the string the watch chain doubled upon itself, and at last the string broke. The boy was directed to drink copiously, and to resist the desire to micturate as long as possible. Fortunately the chain presented longitudinally and was passed with the first force of the full stream.

Mr. Hutchinson, as quoted by Coulson, gives directions for distending the bladder by injections in cases in which the symptoms are not urgent. Several cases are recorded in which different articles have been ejected from the bladder after repeated attempts to find and extract them have been fruitless.

Since the establishment of the greater tolerance of the bladder of operative interference such failures are less likely to occur. It is perhaps well to know that such attempts to induce the bladder to empty itself are occasionally successful, as it does not leave a man entirely helpless who does not possess proper instruments for extraction. Possibly Dr. Bigelow's straight tubes and repeated washings might be of service with certain small substances.

Cases left to themselves are not always by any means so fortunate in results, as in a case from Cooper's Surgical Dictionary: a surgeon, during catheterization of a female, was noticed to exhibit signs of confusion. He quitted his patient abruptly. The same day he left his home, and was never seen afterwards. The lady's urinary difficulty continued for several years until an abscess in the sacral region gave exit, to the astonishment of all concerned, to a blackened female catheter.

Mr. Harrison figures in his *Urinary Surgery* a head of meadow foxtail grass with a long portion of the stalk. It had been passed into the bladder, through the coats of which the stalk passed into the peritoneal cavity, causing peritonitis and death.

Articles introduced into the male urethra seem to have a tendency to pass into the bladder; certain it is that a small body once beyond the meatus is most likely to fall at last into the bladder. An attempt at an explanation was made by Christopher Heath, in 1866, in a short article on the endoscope. "I have noticed," he writes, "in perfectly healthy urethrae that there is a constant vermicular contraction of the wall of the canal, apparently passing towards the bladder, and this accounts for the well-known fact that foreign bodies in the urethra tend to pass in that direction. This is wanting in cases where any induration exists."

Sir Henry (then Mr.) Thompson took exceptions to

this statement, and maintained that the motion was in exactly the opposite direction and that foreign bodies have a strong tendency to pass outwards to the meatus and not inwards to the bladder. Several letters were exchanged but without any positive settlement of the question at issue.

The tendency of deposit to form about the central portion of an elongated object is hinted at by the deposit on the pencil, which is much thicker a short distance from the pointed end than at either extremity. Probably the roughened spot left by the knife in sharpening the pencil was the first point upon which deposit was made. The ends must naturally be subject to more or less attrition unfavorable to deposition. In certain cases, however, the deposit has taken place at the end.

An article on Foreign Bodies in the Bladder, in 1856, by M. Denncé, was copied from a French journal into the *Medical-Chirurgical Review*. The writer had collected particulars of three hundred and ninety-one cases. In closing his article the author compares the termination of cases prior to and after the introduction of lithotripsy. Before 1830, when lithotripsy may be considered to have been generally established as an operation, but four cases of extraction were recorded in the male and sixteen in women to one hundred cases of lithotomy for similar causes; while from 1830 to 1856 forty-six cases of extraction in males and twenty-seven in females are recorded, while lithotomy had sunk to twenty-one times, — a marked progress in favor of the less serious method.

An equal improvement is shown since his day when we compare his remark that "urethral lithotomy is generally to be preferred in women, but we must remember that in women the urethral operation is almost always followed by incontinence of urine, and the vaginal by vesico-vaginal fistulae," with our present method of extraction through a rapidly dilated urethra and our more successful means of dealing with vesico-vaginal fistulae.

A MEDICAL SKETCH OF LIMA.

BY A. C. BEFFINGER, M. D.
Passed Assistant Surgeon United States Navy.

It is seldom that our medical periodicals contain notices of medicine in South America, and indeed there is so little progress that it is rarely necessary; a sketch of the history and present state of the profession in Lima, the most advanced city on the west coast, may not, however, prove uninteresting to the readers of the JOURNAL.

The medical history of Lima dates from the sixteenth century or from the founding of the *University of San Marcos* by royal decree of Charles V., May 12, 1551. Twenty years later Pope Pius V. conceded special privileges to this off-shoot of Salamanca, and the title was changed to *The Royal and Pontifical University of San Marcos*.

The first university of the new world was established at the instigation of the Dominican friars, who controlled and supported it during its infancy, and for many years thereafter. Its scope was sufficiently comprehensive even for a much later period; it embraced the classics, the sciences, and professions, and polite learning in general. It was probably the first school west of the Atlantic to give medical instruction and issue medical diplomas, which privileges it held exclusively, in Peru, for two and a half centuries.

The medical department of San Marcos was under the control of a medical council, termed the proto-medico, whose presiding officer, the proto-medico, had almost absolute powers. It flourished for nearly a hundred years, but gradually declined in company with the other departments, and became defunct about the beginning of the present century. An honorary proto-medico, however, continued to exist, and through its influence the present School of Medicine was founded in the year 1810 by the Viceroy Abascal, under the title of *Colegio de San Fernando*, which was subsequently changed into that of *Colegio de la Independencia*. The school remained subject to the direction of the proto-medico till, by government decree, 1856, that body was abolished and replaced by the faculty of medicine of the University of Lima, the old proto-medico becoming the new dean.

Dr. Gayetano Heredia was the last of the proto-medicos, and the first dean; his praises, as sung by his pupils, show him to have been an able physician and scientist, with views much in advance of his age.

Immediately after the organization of the faculty the *Colegio de la Independencia* became the *Escuela de Medicina*, which name it bears at the present time. This is the only medical school in Peru, yet the yearly graduates do not number over twenty-five, the long course, seven years, influencing students to seek their medical education in countries where the goal is reached in a shorter time. The teaching ought to be good, for the faculty have been chosen since the presidency of Dr. Heredia by competitive examination. When a vacancy occurs candidates are invited to compete for it, each one being required to submit a written theme, deliver an oral composition, and finally an oral argumentation; the examiners selecting by ballot, presumably, the most deserving man. The duties of the faculty, as determined by government decree, are to manage the medical school, examine candidates for physicians and surgeons, pharmaceutical chemists, dentists, matrons, and phlebotomists, and test the qualifications of foreign physicians.

It may be useful to state here for the information of any of your readers who may contemplate settling in Peru, that before being allowed to practice they will have to pass an examination, conducted in Spanish. The professional tests need frighten no one, and very little Spanish suffices, in fact only those wishing to practice in Lima and Callao present themselves for examination, as in other parts they are never called upon for the faculty certificate.

The following scale of prices I have taken from Señor Fuentes' Statistics of Lima, from which source, indeed, I must acknowledge much valuable information:—

Por el diploma de doctor en medicina y Cirujia	\$125.
“ “ farmaceutica	\$60.
“ “ dentista	\$50.
“ “ matrona	\$30.
“ “ flebotómico	\$25.

It is rather amusing to see the M. D. placed in a diploma classification with the ancient phlebotomist, but was it not a wise move to make the apothecaries, dentists, and matrons subject to examination and control by a government faculty of medicine?

On September 7, 1854, twenty-three of the leading physicians of Lima met in the hall of the university, and organized the *Sociedad de Medicina*. The objects of the society were, (1) the advancement of medicine

in general; (2) the advancement of medicine in its special requirements in Peru; (3) the maintenance of the rights and dignity of the profession. The founders of the society deserve much praise for their energetic endeavors to make it a success and real benefit to their country. An official organ, the *Gaceta Medica*, was started, that the views of the society might penetrate all parts of the republic, but it soon languished, and from a weekly journal became a monthly, then was only published at irregular intervals, till 1866, when four of the most enterprising members took hold of it, and not only restored it to its ancient credit, but made it a really useful and instructive periodical.

The *Gaceta* now contains interesting American and European reviews, original articles and statistics upon national medicine, hygienic notices of the coast, etc., etc., which, if read by the Peruvian practitioner, would prove a great boon to his now unfortunate patients. The Society of Medicine, and *Gaceta Medica*, as far as I can learn, stand alone in Peru, and are likely to continue so for some time to come. In 1827 a few venturesome spirits started the *Anales de Medicina*, but a speedy reproof followed their temerity, for the organ died after a year's shameful neglect by the profession.

The hospitals of Lima, with but a single exception, the *Dos de Mayo*, deserve scarcely a passing notice. The great necessity for a large city hospital with modern appointments, was severely felt during the yellow fever epidemic in 1868, and immediately afterward the Municipality of Lima invited plans and proposals for the construction of one. It was determined to name the new hospital *Dos de Mayo*, in honor of the victory over the Spaniards, May 2, 1866, in the bombardment of Callao. Excellent judgment was exhibited in the selection of a design, unique, and in every way adapted to the country. The foundation was laid in 1869, and the building completed and occupied in 1870.

The construction is upon the pavilion system, the plan embracing eighteen wards, two to each pavilion, radiating from a circular patio, and connected at their inner extremities by a portal.

The patio is made into a lovely flower garden, and the spaces between each pavilion are decorated with flowers, walks, and rustic seats.

Twelve of the wards are public and contain fifty-five beds each, the remaining six being private or paying, and accommodating about twenty-four patients each; thus the hospital will dispose comfortably of about eight hundred patients. The ventilation is excellent, the absence of rain and the equable temperature permitting constant perfusion by the southern sea winds, which blow moderately the year round. The water supply is drawn from the Rimac River several miles above the city, and, with the exception of a little hardness, is pure and cold. The sewage system is good, and efficient, the value of secure trapping and frequent flushing being fully appreciated.

The administration is by the Sisters of Charity, a Sister Superior being in charge, with sixty assistants. They keep everything scrupulously clean, and their nursing is all that could be desired. There are two internes to each ward, who serve one year. They are students in the Medical School and are selected in the main by favoritism, as a consequence of which their service is by no means efficient.

Their medical staff consists of seven members and two auxiliaries, and as the practice is general, each member is physician, surgeon, and specialist. These

gentlemen are well selected, and represent the best talent in the city, several of them being professors in the Medical School.

The following statistics are for the year 1879.

Number of patients remaining from previous year	494
Admitted during the year	7927
	<hr/> 8421

Of these, 7339 were discharged, 681 died, and 401 remained at the end of the year. Of the total 8421 there were 8088 non-paying, and 333 paying, patients.

The total number of sick days was 200,663, giving a daily average of 549 inmates. A little over eight per cent. of the whole number died; the causes of death being as follows:

Pulmonary affections	{ Phthisis 279
	{ Pneumonia 92
	<hr/> 371
Dysentery	90
Hepatitis	35
Pernicious fevers	34
Alcoholism	10
General affections	141
	<hr/> 681

The large number of deaths from pulmonary affections reminds one of Boston statistics, and would seem out of place in this latitude, but the intense humidity of the atmosphere due to the fogs which prevail here nine months in the year, readily explains it.

The expenses of the hospital amounted to \$107,860.11, making the value of each ration \$0.537.

The other hospitals of Lima may be briefly touched upon.

The *Santa Ana* is the general women's hospital, but is an old building, ill-suited for the purpose. It contains twelve wards, and is capable of accommodating about five hundred patients. It is served by twelve Sisters of Charity, who take excellent care of the patients and wards. Here, as at home, the sewing-machine victims present a goodly share of the womb cases; and the great color cast in the population adds noticeably to the ratio of fibroids.

There are five officers upon the medical staff, who have their hands full.

Attached to the *Santa Ana* is a small lying-in hospital, in which about one hundred parturients are delivered yearly.

There were 10,556 patients treated in the *Santa Ana* during 1879, with 676 deaths, phthisis and pneumonia, as usual, taking the lead.

San Bartolomé is the military hospital, though originally intended and used for sick negroes. It contains ten wards for privates and two for officers, the total capacity being about nine hundred. The administration is by the Sisters of Charity, and is exceedingly bad. The patients are poorly cared for, and the wards filthy. In one ward was observable typhus, typhoid, and erysipelatos patients mixed indiscriminately with the recently wounded. Overcrowding was the rule, and a death-rate of fifteen per cent. criminally accused the management. There being no medical organization in the army, the staff of the hospital is composed of civilians, and numbers sixteen. The want of experience in military surgery and discipline in these gentlemen was evident in every part of the building, and seemed to be the cause of the total badness of things. The charge of several hundred soldiers needs the discipline of the officer, as well as the care of the surgeon.

The statistics of San Bartolomé are very meagre; no advantage seems to have been taken of the surgical offerings. During 1879 there were treated 529 officers and 9,731 men; of these, 493 officers and 8,473 men were discharged, and 4 officers and 122 men died. The statistics for 1880-81 will show very differently, but I doubt if they will ever be published truthfully.

There are a half-dozen more small public and private hospitals, not necessary to enumerate, and many public buildings have been converted into provisional ones since the campaign upon Lima. There are at present at least three thousand Chilean and Peruvian wounded distributed among the various hospitals, but not the slightest benefit to surgery can be hoped for in all this wide field. There are not ten capable surgeons in the entire Chilean army. The weakness and inefficiency of this service brought a most interesting case of strangulated scrotal hernia under the care of Surgeon C. H. White, U. S. Navy, the successful treatment of which warrants its record. The man was a trooper, and was thrown from his horse during exercise, producing a strangulated scrotal hernia of the left side. Dr. White chanced to be on shore at the time, and was called in consultation. The Chileans were at a loss what to do, so Dr. White took charge of the case. After several hours' fruitless efforts at reduction by the usual method, aspiration was decided upon, the needle being passed into different parts of the tumor, which immediately began to diminish, and in a few minutes was not more than a third of its original size. The needle was then withdrawn, and a slight taxis at once effected reduction. The patient was seen eight days afterward, and was doing splendidly, not the least constitutional trouble having followed.

I have not heard of this treatment being used before, and its rapid and complete success entitles it to general consideration.

Hospital Practice and Clinical Memoranda.

UNUSUAL URETHRAL CASES.¹

BY C. B. PORTER, M. D.

TRAUMATIC STRICTURE, WITH FOREIGN BODY IN PROSTATIC URETHRA; PERINEAL ABSCESS.

CASE I. J. R. The patient was thrown from a wagon sixteen years ago, striking astride the wheel. Passing water shortly after he found it extremely bloody and the act very painful. For several days this bloody urine persisted, gradually growing fainter in color until at last all traces of blood disappeared. Before long he noticed there was some difficulty in micturition, especially in starting the stream. He delayed consulting a surgeon until matters had advanced so far that he was obliged to pass water at very short intervals, often rising five to ten times nightly and walking the floor ten to twenty minutes before he could start the stream, which then came only in drops. This was his condition on entrance to the hospital; in addition there was a perineal abscess, so that he was in pain more or less

¹ Read before the Boston Society for Medical Improvement, April 11, 1881.

severe throughout the whole day. The urine was alkaline and full of pus, some blood.

Under ether the smallest guide to the Voillemier was with difficulty introduced, locating the stricture in the membranous portion of the urethra. As it passed in a peculiar grating sensation was felt, suggestive of stone, but no examination was possible until the calibre of the urethra had been enlarged by divulsion, when careful exploration failed to detect any stone, and as the grating was less marked after divulsion it was thought to be probably due to a deposit of phosphates from the alkaline urine on the wall of the urethra. A catheter was fastened into the bladder and the perineal abscess opened.

During convalescence the patient declared from day to day there was constant improvement in his symptoms, that the pain was gone, and that he could retain his urine without difficulty, but still there was almost no change in the character of his urine. At the end of a week the sound was passed to ensure patency of the stricture, and as before it glided over some calcareous body in the vicinity of the prostate; at the same time it was learned that the patient, from dread of operation, had been deceiving about his symptoms, and that the improvement was in reality very slight. The diagnosis was then made of the presence of some foreign body in the urethra, at the neck of the bladder. This opinion was verified under ether. From the position of the body it was impossible to engage it between the blade of the lithotrite or to push it into the bladder, and a staff was introduced and the urethra opened as in lithotomy. A dissection was carefully made through a mass of old inflammatory tissue into the substance of the prostate and a jagged, irregular sequestrum of bone removed from its bed in the prostatic urethra. There was very little blood lost at the operation. While recovering from ether the patient was very violent and noisy and was given a small hypodermic of morphia. Soon he became very quiet, his pulse rose to 132, very soft and compressible, respirations were labored and dyspnoea urgent. There were no evidences of hæmorrhage, either external or concealed, but his condition grew very alarming, and it was only by the use of stimulants hypodermically that he rallied from a state of collapse. The following day the patient was quite comfortable and made an interrupted recovery. The catheter was kept in until the perineal wound was closed, and three weeks after the operation the patient was discharged, the urethra admitting thirty F. Micturition a little more frequent than normal, probably due to a contracted bladder, but painless and free. Urine normal. Subsequent reports from the patient state that there is no return of his old symptoms.

CASE II. S. F. The patient has known that he had stricture for fourteen years. In that time he has had retention many times and has been operated upon by divulsion at least twice, but has never been taught to keep his stricture open. He admits only the smallest capillary. This was passed daily from March 9th to March 12th, then a fair sized guide to Voillemier was introduced and the stricture divulsed, after slitting the meatus. The stricture was extremely difficult to split and a catheter could not be introduced afterwards, seeming to catch on a fold of mucous membrane. Soon after the operation he passed his urine in a large stream. During the night he had a severe chill which did not yield to the ordinary remedies, and at the morning visit he seemed very sick. Temperature

104.4° F. Pulse rapid and soft, skin hot, very restless, and severe pain referred to base of sternum. At eight A. M. he passed a few drops of urine when on the bed-pan. This was all he passed except that just after the operation. One sixth of a grain of nitrate of pilocarpin was given hypodermically; this immediately induced profuse diaphoresis which continued several hours and from which he experienced great relief. Stimulants and counter irritants over the kidney were kept up through the afternoon and evening, and the condition of the patient seemed rather better. At four P. M. temperature 105.3° F. At six P. M. 100° F. No urine, however, was excreted and the pain at tip of sternum persisted. At midnight, quite suddenly, there was a change for the worse. The pulse became quite imperceptible. The face grew livid and respirations labored, and there was no response to stimulants. At times there was slight delirium, but usually the mind was clear. There was very little vomiting. There was steady failure of the vital powers, and patient died forty-four hours after the operation. No autopsy could be procured, and the case was considered one of urethral fever, with probable surgical kidney. Thomson¹ seems worthy of quotation in this connection.

"There are some patients, the subjects of stricture, who invariably experience rigors after the passage of a bougie, or if an instrument but one number larger than the accustomed size be passed; in some, even without any apparent exciting cause, more especially in those who have inhabited warm climates for any length of time, these attacks are prone to occur. The application of an irritant or corrosive substance to the urethra is also not uncommonly followed by some general fever. So well known and characteristic is this phenomenon, that it has received the special name, and not inappropriately, of 'urethral intermittent fever.' It may occur in the absence of stricture from various kinds of irritation to the canal.² In many instances it occurs only after the first act of micturition following the application of the irritant, as if from contact of urine with the abraded urethra, or with the wound, if the incisions have been made.

"I have, however, frequently noticed that when evidence of organic renal disease exists, the symptoms described are almost certain to occur; so much so that we are justified in suspecting its presence to some extent when severe rigors constantly follow slight urethral irritation in patients not predisposed, by climate or otherwise, to experience them, and who have suffered for some time from stricture. I have observed on more than one occasion suppression of urine, rapidly followed by death, to result from the introduction of an instrument larger than the patient has been accustomed to, in the hands of a surgeon who, from some accidental cause, has replaced the ordinary attendant, and who has unwittingly endeavored to carry dilatation beyond the usual limit; or, again, when the ordinary instrument has been less skillfully employed, and an abrasion, although only an exceedingly slight one, has been made in the mucous membrane of the urethra. The rapidity with which death may occur, under these circumstances, in patients who are the subjects of extensive chronic disease of the kidneys, from an apparently exceedingly

¹ Stricture of the Urethra, page 111.

² M. Chassaignac has made the observation, that the "urethral intermittent" occurs from some irritating contact with the *bulbous* and *anterior part* of the urethra, not with the prostatic and membranous portions; remarking that thus it never occurs in women, whatever the amount of instrumental application. *Mon. des Hop.*, 1857, No. 135.

trifling lesion so caused, appears almost unaccountable. The fatal event seems to occur through poisoning of the system by urea: the post-mortem appearances, to the naked eye, do not resolve the problem in the cases referred to, by exhibiting traces of acute disease resulting from the particular lesion. It may be imagined that the function which determines the elimination of urea suddenly and absolutely ceases after a very slight injury to the urethra, as by the propagation of some shock to the excreting organ, in cases where its structure is largely disorganized. I have even seen one case of old standing and narrow stricture, in which death was thus caused within fifty-four hours of the passing of an instrument, the same that had been habitually employed on at least a hundred occasions before, no damage whatever having been inflicted by it upon the urethra, as verified by several careful observers on close post-mortem examination of the parts. Rigors and vomiting commenced about an hour after the catheterism, and not another ounce of urine was secreted from that time until death. In this case the kidneys were found to be congested to an extraordinary degree, and their substance was so soft and friable as to give way under gentle pressure. Very rapid changes had evidently taken place in these organs, but no signs whatever of inflammation existed in any other part of the urinary apparatus. So also a catastrophe, equally, but not quite so rapidly, fatal, may happen from another affection, namely, purulent infection of the blood, with deposits in the joints or other parts, and which may occasionally happen as a result of injury to the urethra inflicted by rapid or extreme dilatation."

RETENTION, STRICTURE, PUNCTURE PER RECTUM,
PERITONITIS, DEATH, ABNORMAL ARRANGEMENT OF
THE PERITONEUM.

CASE III. J. K., aged twenty-five, entered hospital April 5th, at three p. m. He had passed no urine since the previous day. Attempts had been made by two doctors outside to draw it but without success, and in consequence of their efforts he had bled considerably. The overdistended bladder was prominent above the pubes, extending well up towards the umbilicus. Under ether an attempt was made to introduce a small catheter which brought up against a stricture in the membranous urethra, and the capillary guides to the Voillemier entered only false passages. Examining by the rectum the bladder was prominently bulging down and the rectal trocar was thrust into it just at the apex of the triangle formed by the prostate and vesiculae seminales. The urine at once flowed freely through the canula, and the amount, although not accurately measured, was not less than three pints. As there was no soft rubber catheter small enough to pass through the canula, a gum-elastic bougie catheter was introduced and tied in, through which the bladder was entirely drained. At six p. m., two hours after the operation, the patient was perfectly comfortable, at twelve he was sleeping quietly and the bladder entirely empty.

April 6th, four a. m. Patient suddenly complained of most intense pain just at the tip of the sternum, extending towards, but not beyond, the umbilicus. He was relieved by hot fomentations and one eighth grain of morphia. There was no collection in the bladder, no tympanitis, and very slight tenderness.

Eight a. m. After a few hours' intermission the pain returned, not very severely, however, but the patient

looked very sick. His facies was that of threatening collapse, with a fast and feeble pulse. There had been no flow of urine through the catheter since four a. m.

Eleven a. m. Patient had rallied considerably and was both feeling and looking better. He had passed four ounces of urine through the penis, and was taking nourishment very well. The bowels had moved three times. Throughout the day there seemed to be a continued improvement in his condition. The pain had entirely disappeared, leaving only a sense of soreness, and up to four p. m. he had passed twelve ounces of urine through the natural channel.

Half-past eight p. m. As in the morning he had suddenly intense pain, which in a few minutes was eased by one sixth grain of morphia that he fell asleep.

At nine p. m. he woke, asked for a basin, which he nearly filled with vomitus and fell back dead, thirty-four hours after operation.

In his history he stated that he had had gonorrhœa twice—once many years ago, and the last time three years ago. Since the last attack he has noticed a diminution in the size of his stream with greater difficulty in passing it, and eight months ago he had retention, which was relieved by the introduction of a small catheter.

From four p. m. until he died, at nine, there was no urine passed, and as the autopsy showed an empty bladder there must have been suppression during that time.

AUTOPSY.—*Lungs.* The pleura were somewhat thickened, and adherent by strong fibrous bands, especially on the left side. On both sides they were injected and covered with a layer of fibrin, which at the bottom of both cavities had collected into masses. The lung tissue was normal except for post-mortem œdema.

Heart. Results of acute endocarditis seen, especially marked at the bases of mitral and bicuspid valves.

Liver and Spleen. Normal.

Intestines. When the abdomen was opened the omentum and intestines showed most vivid injection, and were covered with a delicate membrane, with here and there more opaque spots of a thicker deposit, but were nowhere adherent to each other. Moving the coils one side, the pelvic cavity was seen filled with pus of creamy consistency, amounting, with what little serous exudation there was, to six ounces. Other than inflammation of the peritoneal coat the intestines were normal.

Bladder. The bladder was contracted to the size of a large English walnut. Between the bladder and the rectum the peritoneum lay in a series of rugæ, beneath one of which was a perforation, a little larger than a knitting needle, leading into the rectum.

Pelvic and External Organs. The lower part of the rectum, the kidneys, ureters, and penis were removed entire. Passing a probe through the opening made by the trocar in the rectum it went directly into the bladder just below the opening of the left ureter, or, if it were directed a little backwards, entered the peritoneal cavity with equal ease through the perforation mentioned above. The bladder contained no urine, but about half a drachm of pus. The walls were much thickened, and the mucous membrane of dark-blue color.

Kidneys. Kidneys congested but otherwise normal.

Penis. Opening from the meatus a healthy urethra was exposed until the membranous portion was reached, beyond which the scissors could not be advanced.

Cutting from the bladder outward the urethra was traced to a minute opening into its anterior portion, not in the median line, but high up on the left side. The anterior portion terminated in a large false passage, which showed evidences of recent laceration.

This case died from peritonitis, induced, probably, by wound of the peritonæum in puncture of the bladder by the rectum. Upon examination of the specimen, and the arrangement of the peritonæum at the base of the bladder, this is readily explained. Normally, the peritonæum is reflected from the posterior surface of the bladder to the rectum, leaving the triangular space bounded in front by the prostate and on the sides by the vesiculæ seminales resting upon the rectum and free from peritonæum. Gray states that in the distended bladder the distance from the anus to the point of this reflection is four inches. Roser, in his *Surgical Anatomy*, says: "In adults there is a pretty good interval from the edge of the prostate to the inferior extremity of the peritonæum." Quain states: "In front of the line of reflection of the serous membrane, the base of the bladder is destitute of peritonæum and adherent to the rectum by dense fibro-areolar tissue over the extent of a triangular area bounded at the sides by the vasa deferentia and vesiculæ seminales, whilst its apex in front reaches the prostate gland. It is in this space . . . that the bladder may be punctured from the rectum without injury to the peritonæum." Other authorities might be quoted to confirm the arrangement just described as the normal one. In my case the peritonæum passes down more deeply than usual, covering entirely the triangular space, and in the state of non-distention reaching the prostate, and the only wonder is that it was not punctured twice on the way to the bladder, instead of being simply nicked.

A parallel case is reported by Berkeley Hill in the *Lancet*, August, 1876, page 187.

"At the post-mortem examination extensive general peritonitis was found, most intense at the pelvis. The pelvic viscera were removed in one mass. The recto-vesical pouch of the peritonæum (very long) was found to extend completely past the trigone of the bladder and to reach quite up to the prostate; accordingly, both the punctures from the anterior wall of the rectum to the trigone of the bladder passed twice through the peritonæum. A very tight stricture occupied the membranous and bulbous part of the urethra, which only admitted a fine probe. A short, false passage passed into the dense tissues surrounding the urethra. The tissues of the perinæum were immensely thickened, and traversed by a narrow fistula from the urethra just behind the stricture to the wound in the perinæum. The prostate was enlarged; the bladder distended, hypertrophied, and sacculated. The mucous membrane was dark-colored from old cystitis; it was marked with two trocar punctures at the trigone, about half an inch in front of the orifices of the ureters, but near the middle line, and half an inch behind the prostate. The ureters and pelves of the kidneys were also greatly enlarged, the kidneys much wasted by interstitial nephritis."

TRICHINOSIS. — *Punch* thus trifles with serious matters: —

"Says Aaron to Moses,
'I have got trichinosis';
Says Moses to Aaron,
'Tis because you pork fare on.'"

CASE OF INTUSSUSCEPTION OF THE LARGE INTESTINE.¹

BY C. P. PUTNAM, M. D.

JAMES A. H., five months old, nursed on the breast, and perfectly healthy until February 10, 1881. On that day, about two P. M. he had cried and twisted in such an unusual and peculiar way that it was supposed a pin might be sticking into him, and he was undressed to get rid of it. Soon after he had a solid defecation, followed by much straining, and a discharge of liquid blood. Before long he vomited, and though he took the breast he continued to vomit at intervals. When first seen, about twenty-eight hours after he was attacked, he had had about eight stools consisting only of blood.

He looked languid; the legs were flabby; he nursed a little while when the breast was offered, but soon gave it up, and generally vomited a brown fluid, which had no stercoraceous odor.

The muscles of the abdomen, like those of the legs, were quite flabby, and the abdomen could be thoroughly explored. A cylindrical tumor, about three inches in length and one and a quarter in diameter, was to be felt between the umbilicus and the left costal cartilages, and parallel to the latter, which suggested nothing but an invagination of the bowel. It was easily movable within narrow limits, and occasionally would fall so far back under the liver as to be hard to find.

Gentle massage was applied to this tumor with the intention of diminishing the hyperæmia and edema, and possibly of reducing it. It was evident that the former of the two ends was attained, for the tumor became softer, and it seemed as if it became a little shorter. Water was then injected into the bowel by means of a douche pail, which was held by a man as high as his head when standing on a chair, making a column of about five feet. The water was prevented from returning through the distended anus by an arrangement to be described. The pressure was kept up about two minutes, but on allowing the water to flow out of the bowel the tumor was still there, though perhaps somewhat smaller than before. A second attempt appeared to be more successful. The pressure was kept up somewhat longer, and at the end of it no tumor could be found, and the child nursed without vomiting, and went to sleep. This was at ten P. M. Towards morning there were three bloody stools, and the tumor was found in the same condition as on the previous evening. The abdominal walls, however, were less flaccid, and the skin was hot; the temperature 101° F. The water was again injected, and the pressure kept up until the child began to get livid, and the respiration was seriously interfered with. When the water was let out the tumor was not to be felt. One drop of deodorized tincture of opium was given every two hours unless the child was quiet. He slept a large part of the afternoon, and at eight P. M. passed a liquid stool of stercoraceous character. From this time he appeared perfectly well.

It is not easy to make a plug for the anus that will fit everywhere and not press too hard anywhere. In this case a very soft rubber bulb, such as is used with the hard atomizer, was employed in such a way that the water flowed into it by one tube, and out again by

¹ Read before the Boston Society for Medical Improvement, April 11, 1880.

another tube, which went into the rectum. By this means the bulb was distended by the same pressure that was exerted on the inside of the rectum, and by holding the bulb firmly against the anus exactly the required pressure was obtained. For if the bulb was not pressed on hard enough the water would flow out round it, and if it was pressed on too hard the bulb would collapse.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

APRIL 11, 1881, DR. T. B. CURTIS presided.

FOREIGN BODIES IN THE BLADDER.

DR. POST read a paper on this subject. Vide page 365 of this journal.

DR. C. P. PUTNAM mentioned the case of a manservant who, thinking that he had retention of urine and that it was from a stricture, made use of a bodkin which, as he expressed it, was "sucked in" and could not be withdrawn. Dr. Putnam found no difficulty in extracting it.

DR. T. B. CURTIS showed a list of three hundred and ninety-two foreign bodies in the bladder, collected by Dr. Mignon, and cited by Dr. Charles Monod in his articles upon Foreign Bodies (*corps étrangers*) in the *Dictionnaire Encyclopédique*, which was evidently the same referred to by Dr. Post.

Dr. Curtis also recalled a curious case related by Dr. E. L. Keyes.¹ Speaking of Squire's "vertebrated catheter," and of the danger attending its use, Dr. Keyes gave as an instance the case of an old man who had long employed this catheter upon himself; the chain had given way in two instruments successively, leaving all the links in the bladder; but the patient nevertheless still desired to procure another catheter of the same description. In 1877 Dr. Curtis saw, among the out-patients of the Massachusetts General Hospital, a man who, a year before, procured a vertebrated catheter; on using it for the fourth time it came to pieces in the urethra, and all the links, fifteen in number, had to be extracted from the canal with forceps, at the Salem Hospital.

URETHRAL CASES.

DR. PORTER reported some exceptional urethral cases. (See p. 370.)

Commenting upon Dr. Porter's case of urethral fever, DR. CURTIS called attention to the circumstance, mentioned by the reader, that the patient, after his first operation for stricture, had not been instructed to use a bougie at suitable intervals during the remainder of his life, and had, therefore, before long undergone a relapse, rendering necessary a second operation, which in such cases was very apt to prove fatal. This history is a very common one in the experience of hospital surgeons. It is the duty of the practitioner, when treating stricture by urethrotomy or by division, not to content himself with merely restoring the ability to urinate freely; but he should also render the urethra sufficiently patent and pervious to allow of easy self-catheterism; and furthermore, he should take pains to instruct the patient fully, with regard to the subsequent

indispensable use of the bougie, and forewarn him of the dangers attending neglect of this simple prophylactic measure.

The reader had quoted a passage on urethral fever from Sir Henry Thompson's work on Stricture, in which it was asserted that the fatal event seemed to occur through poisoning of the system by urea. It should be observed that no proof whatever had ever been adduced to show that the retention of urea was the cause of the severe febrile symptoms observed in such cases. Uremia, far from being a pyrexial disorder, is almost invariably attended by abnormally low temperatures, often considerably below the normal, as has been abundantly shown by Bourneville, Charcot, Roberts, Girard, and others.

DR. GREENOUGH asked if the urine in Dr. Porter's second case was ammoniacal, and remarked that he had heard Oppolzer speak of the danger of operating in these cases where the urine is ammoniacal or decomposed.

DR. PORTER replied that the urine had not been examined in this case.

In connection with Dr. Porter's case of fatal peritonitis following the rectal puncture of the full bladder, and due to perforation of the peritoneal pouch, descending in this case abnormally low between the floor of the bladder, seminal vesicles, and prostate in front, and the rectum behind, DR. CURTIS, who had mistrusted the recto-vesical puncture ever since the publication of Berkeley Hill's case in 1876, showed three large lithographic plates, in Jarjavay's monograph on the anatomy of the urethra, representing life-size, median, antero-posterior sections of the male genito-urinary organs, made in frozen bodies. A copy from a plate in Braune's Atlas, representing a similar frozen section, was also shown. From an examination and comparison of these four sections it was evident that the disposition of the peritoneum in the pelvic cavity, and its relations to the bladder, were subject to much variation; in some individuals the peritoneal cul-de-sac between the bladder and the rectum descends much lower, much nearer to the anus, than in others, and is much more accessible to the finger and to the trocar.

INTUSSUSCEPTION.

DR. C. P. PUTNAM reported a successful case of intussusception. (See page 373.)

OVARIOTOMY.

DR. JOHN HOMANS showed two tumors, removed a week ago, from a single woman, aged forty. It was the first time Dr. Homans had operated for the removal of a solid ovarian tumor, and the first time that he had removed a uterine tumor by abdominal section. The patient was a small woman, affected with curvature of the spine and disease of the heart. There was well-marked mitral regurgitation, some hypertrophy of the heart, and more or less cyanosis of the face and hands, with a weak, radial pulse. After some weeks of preparation and administration of digitalis by Dr. E. G. Cutler, who kindly undertook the preparatory treatment, ether was administered without the slightest embarrassment, and the operation was easily performed. First, the solid ovarian tumor was raised through an incision extending from a couple of inches above the umbilicus to the pubes; the dermoid cyst (described below by Dr. Gannett) was attached to the lower part of this solid tumor, and had the usual ova-

¹ New York Medical Record, May, 1877, 235.

rian pedicle. After the pedicle had been secured, the fibroid tumor was lifted up and found to be continuous with the fundus of the uterus; but there was a rather narrow cystic portion just above the fundus of the uterus, and Dawson's clamp was applied, and this cystic portion compressed and divided by Paquelin's cautery, and the stump tied. Since the operation the temperature has risen but once above 99° , and the patient bids fair to recover rapidly. The uterine cavity was not opened. Dr. Homans read Dr. Gannett's excellent description of the tumors.

The following is Dr. W. W. Gannett's report of the specimens.

Uterine Tumor. Size of a big fist [8 c. m. \times 10 c. m. \times 10 c. m.] and weighs 491 grammes [17½ oz.], very dense, external surface lobulated and irregular, with a few small vessels. On cutting into, found to be very dense, the tissue creaking under the knife. The cut surface presents a striated appearance, some portions being white, others of a pinkish tint. Towards the periphery a cavity with irregular walls, capable of containing about 5 c. m. fluid. *Microscopically* the tumor found to be made up of bundles of large, nucleated, spindle cells and connective tissue fibres, running in various directions. *Diagnosis*, Fibromyoma.

Ovarian Tumor consists of two portions, a larger and a smaller. The larger is a more or less globular growth, size of a child's head [16 c. m. \times 12 c. m. \times 12 c. m.], and weighs 1080 grammes [38 oz.], is rather dense, capsule smooth, and in it several large vessels. In some portions the external surface has a homogeneous, opaque, pinkish appearance, in other places a peculiar gelatinous appearance. On cutting into these gelatinous places they are found to be perfectly transparent and yield a slight amount of an albuminous but not mucous fluid. Section of the tumor, as a whole, shows an almost homogeneous, flesh-like, rather moist, surface of a pinkish-white color. On pressure, the surface yields a small amount of clear fluid similar to that just described.

Microscopically, found to be made up of small spindle cells with oval nuclei and very delicate protoplasm, and also an intercellular substance made up of connective tissue; in some portions this connective tissue is in the form of delicate anastomosing fibres arranged in a network, with spaces between, in other portions, in the form of wavy fibres arranged in horizontal bundles. The blood-vessels are rather few in number. Sections of the gelatinous portion show an exceedingly delicate connective-tissue net-work enclosing spaces [which contained the previously mentioned fluid].

Attached to this tumor just described, by a small base, was another the size of an orange, of a doughy consistency and from a rent in which there projected a mass of hair and a yellow, curd-like material. This was found to be a cyst with a wall about 2 mm. thick, filled with a yellow material of about the consistency of cream, at the temperature of the body, but on cooling, becoming as hard as butter; microscopically this material found to be fat. In this were very numerous hairs. The inner surface of the wall is in some places white, in other places of a dirty, opaque yellow, and in many places there were hairs projecting from the wall into the cavity of the cyst. In one portion of the inner wall is imbedded a bit of bone size of the second phalanx of a finger, showing spongy structure, and from this project three or four hard bodies closely resembling teeth. The

latter imbedded in a tissue made up, superficially, of a many-layered, flat epithelium, and in the deeper portions of a connective tissue infiltrated with round cells and containing numerous blood-vessels. Sections of the wall of the cyst show a structure closely resembling external skin, a many-layered flat epithelium upon a connective tissue layer. In the latter numerous hair follicles with hairs in them and also numerous sebaceous glands. In some places are groups of very large sebaceous glands and no hairs.

Diagnosis. Fibro-myoma from uterus; small-spindle-cell sarcoma of ovary; dermoid cyst of ovary.

Recent Literature.

Fever: A Study in Morbid and Normal Physiology.
By H. C. Wood, A. M., M. D. Philadelphia: J. B. Lippincott & Co. 1880.

One of the ablest and most interesting records of physiological research done in America has been recently given us by Prof. H. C. Wood, of Philadelphia, in a monograph on Fever. This memoir is the result of many years of study, and must have required an immense amount of time and patient labor. The experiments are numerous, and were conducted with scientific rigor. The deductions made from them are logically and carefully drawn up, and the conclusions reached are presented as matters of firm conviction and belief. The work is a model of skillful physiological investigation. The expense of publishing was assumed by the Smithsonian Institute, which is in itself a compliment. The details of the subject are so interesting that they deserve a longer review than we can give them at this time, and accordingly we shall notice the book again and at length in the next report on Physiology. G. M. G.

—A curious suit against a physician, which illustrates one of the perils of the profession, was brought to a close lately in Philadelphia. The facts were these: a man having been injured by a street car passing over his limbs, a passing physician's carriage was stopped, and the physician — who happened to be Dr. William B. Atkinson, the affable permanent secretary of the American Medical Association — made to descend and give an opinion as to treatment. The advice given was to send for an ambulance, and have the case taken to a hospital. The man dying a few days later, the widow brings suit against Dr. Atkinson for substantial damages for not yielding more prompt and efficient service to the patient, although no consideration had passed, and no special claim for such service shown to exist. When the case came up Judge Ludlow ordered a non-suit to be entered for the plaintiff. Although this case did not go to a jury where the issue would be uncertain, yet the defendant was put to considerable expense and loss of time, and a great deal of annoyance, by the prosecution, which made it an ordeal to which one would not willingly be subjected. Happily, prosecutions of the profession by adventurers seeking for black-mail are quite rare in this State, Should they become more frequent in the future a physician's life will be anything but a happy one.

Medical and Surgical Journal.

THURSDAY, APRIL 21, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

Houghton, Mifflin and Company,
No. 4 PARK STREET, BOSTON, MASS.

SPARKS FLYING ABOUT OUR POWDER MAG-AZINE.

Our readers have doubtless seen in the daily papers the account of a poor woman who was found by the police last Monday morning, April 11th, wandering about the Old Colony Station, carrying in her arms a large bundle wrapped up in shawls. Suspicious were soon aroused by her furtive manner, and by her evident desire to conceal the object which she bore. Upon investigation the latter proved to be a child whose skin was covered with a pustular eruption resembling that of small-pox. The mother and child were conveyed to the station-house, the city Board of Health was immediately notified, and the child, soon after examination and confirmation of the suspicions excited by its appearance, was conveyed to the special hospital on Canterbury Street.

This case, taken in connection with the report, which reaches us whilst writing, of two cases of small-pox in Lowell, and of still another case in Boston, very recently brought to the attention of our Board of Health, exemplifies the constant danger in which our community is now living in consequence of the prevalence of small pox in neighboring cities; it also illustrates the almost insuperable difficulties of the task of warding off the epidemic devolving upon our sanitary authorities, and hitherto successfully accomplished, thanks to their ceaseless vigilance and energy. With sparks freely flying from all directions, the chances of an explosion depend, of course, upon the extent to which gunpowder is left lying about, accumulated and exposed. An unvaccinated community is sure, sooner or later, to furnish the material for an epidemic explosion of small-pox, all that is then lacking being a case or two to start the spread of the contagion. To a certain extent, and for a while, perhaps, the community can be protected by the prompt recognition and enforced isolation of such individual cases of small-pox as may make their appearance among us; but this means of prevention is, at best, but aleatory, and may at any time fail us, as came near being the case the other day, when this poor woman was doing her best to escape with her sick child from sanitary supervision and control. The case just alluded to, however, shows how precarious our immunity from small-pox has been and is, and how easily the disease may at any day gain access to our hitherto favored community.

It is our earnest hope and wish that the protective resources afforded by vaccination may have been so

thoroughly and extensively utilized that the epidemic now about us may turn out to have been completely warded off, the flying sparks having failed to alight upon any explosive material. Should this happy but improbable consummation be realized we shall be prepared and consoled for seeing our present admonitions regarded as having been wholly superfluous and uncalled for; for such is not unlikely to be the view which will be taken, should the precautions which we advocate have all the efficacy which we desire and hope for.

THE PLAGUE IN MESOPOTAMIA: TYPHUS FEVER IN NEW YORK.

THE plague is spreading very considerably in Mesopotamia. How soon it will reach New York we will not venture to predict. A nasty custom, dear to the Mussulman inhabitants of Asia Minor, of transporting the putrescent bodies of the devout dead by caravans across long distances to sacred places for interment has been many times accused of favoring the development and spread of the plague in that old-fashioned country. Being an old-fashioned disease it is probably still unaware of the hospitable reception which the peculiar nastinesses of the streets of the metropolis — unique in filth as in much else — of our modern republic would gladly hold out to it; a hospitality not at all exhausted by typhus fever (a disease of which even the Polish provinces of Prussia now see very little), diphtheria, ophthalmia, small-pox, etc.

We wonder if a good active immigration of plague would induce the lower house of the New York Legislature to allow the mayor of New York city, or any one competent individual, to actually clean its streets. Apparently not; for the mayor would still be a democrat, and the appropriation to be spent would still be about a million dollars. Moreover, the mayor is suspected of owning some rather barren acres on Staten Island, and it is surmised that if the excrement and filth were removed from the streets of the city the mayor's country property might be rendered more fertile thereby. Better disease and death a hundred times than profit to a democrat! This is the doctrine of state-rights as expounded by members of the republican party with a vengeance.

THE MEDICO-LEGAL RELATIONS OF HYPNOTISM.

THE fact of the irresponsibility of individuals while in a state of mesmeric trance has long been recognized by the best authorities; but the desirability of having the law take cognizance of the existence of such a condition (by means of which it is in the power of the evil-minded to cause innocent persons to commit crime unconsciously) was brought to the attention of the New York Medico-Legal Society at a recent meeting, when Dr. Hammond sought to give a practical demonstration of the manner in which a proper subject could be made to commit supposed acts of felony with the utmost disregard of consequences. The young man selected for the experiments, having

been put into the trance-state, was first charged to commit a burglary. A brown-stone front house was described to him, having a window in the basement, and in a room up two flights of stairs Dr. Hammond told him there was a chest at the foot of the bed, containing money, which he must steal. Immediately he crawled under a large easy chair, which he supposed to be the basement-window, and climbed up a step-ladder which had been placed against the wall; after which he filled his pockets with imaginary money from the supposed chest, and returned by the same way as cautiously as a genuine burglar would have done. He was then apparently made to believe that he was arrested, taken to prison, released on bail, and finally persuaded to return the money to the chamber from which he took it on the promise of a pardon by the Governor. The subject was next made to commit an imaginary murder. A gentleman standing in the doorway was pointed out to him as the murderer of his mother, and he was told to kill him with a dagger, while a folded piece of paper was handed him to represent the weapon. Obediently to the command he crept stealthily up behind the gentleman, and struck him twice in the back with the paper dagger, which he then threw away. His attention now being called to an angel with a flaming sword, that stood before him as a minister of vengeance, he clasped his hands in terror, and with a shriek threw himself upon the floor. The last experiment was to cause him to forge a check for \$25,000 by imitating the signature of Dr. C. S. Wood, the president of the society. This he did very creditably, and then presenting it at an imaginary bank drew the money on it, as he supposed. To show that the man was not shamming, but really in the trance-state, Dr. Hammond passed a needle through a fold of skin at the back of the neck, and burned him with a red-hot cautery; both of which tests he bore without showing the slightest evidence of sensitiveness.

In the place of hypnotism or mesmeric trance, Dr. Hammond would suggest the word *syggignocism* (signifying agreement with), which he believes describes the condition more accurately than any other. While admitting that many of the facts observed in connection with this state are very difficult to explain satisfactorily, he ventures to advance the theory that during its continuance the action of the superior or intellectual part of the cerebrum is cut off, as offering the most philosophical solution of the problem. All individuals, it is acknowledged, sometimes act in an automatic manner, performing various actions without conscious volition, and without calling into activity the superior portion of the brain. This, he claims, is practically the state of affairs in *syggignocism*; the function of the superior portion of the brain being cut off, but perception and the transmission of impressions down to the muscles remaining. In this condition, while a person would act in accordance with the perception, he would not be able to originate anything,—the transmission of impressions from the gray matter at the base of the brain to that of the cortex, and their elaboration into ideas being inter-

fered with,—and would be completely controlled by another in all things.

Some weeks since we published a report of a lecture by Dr. Beard, in which some of the phenomena of hypnotism were exhibited and described. Dr. Hammond's exhibition was a practical application of similar experiments. We give them without comment as contributions to a subject which at the present time, in various forms, is exciting much attention.

BIOLOGY AT THE JOHNS HOPKINS UNIVERSITY.

THE Johns Hopkins University has lately issued its ninth University Circular. This is especially devoted to biology, details being given of what has already been accomplished, and of the facilities offered by the university for the prosecution of this branch of science, the study of which is so desirable for young men who would lay a suitable foundation for the subsequent study of medicine.

It was the wish of the founder of this university, and of the hospital likewise bearing his name, that the two should coöperate in the promotion of medical and sanitary science. It has been the purpose of the trustees to put this wish into execution, and in the judicious pursuit of this end, the time in their estimation not yet having arrived for the appointment of a medical faculty or the announcement of professional courses of study, their first care was to give a thorough foundation for such courses by instruction in physics, chemistry, and biology. Under the term biology, as understood by the university, physiology and morphology, both animal and vegetable, are included. There is no lack of medical schools, such as they are, in the country now, but there is a want of preliminary scientific training which shall fit men to make the most of subsequent advantages. The authorities of Johns Hopkins University, moreover, deserve the thanks of all interested in the best application of that noble foundation to the public good for the adoption of the general policy that, when a choice is possible between two subjects in which to afford special facilities for the most advanced study and to encourage research, the one should be selected in which such facilities are less commonly met with elsewhere in the United States. In this way an attempt is made rather to complement than to rival the work of other institutions, whether giving preliminary or higher instruction.

It is a pity that this same admirable policy has not been more generally cultivated in this country by founders and trustees. It is in these matters that our country exhibits preëminently the want of economy of force so characteristic of youth.

The university allows an undergraduate student to select his plan of study from any one of several schedules. Among the subjects which he may take up, after studying physics and chemistry, is biology, and this study is recommended to those preparing to enter subsequently upon the professional study of medicine. A systematic course of instruction has been thrown

open to those who do not intend to take the B. A. degree, who intend hereafter to study medicine, and who can pass an entrance examination showing a fair general education. This practically extends the time occupied in medical studies, and gives a sound scientific education as a basis for them.

The regular course of instruction in biology for undergraduates comprises, the first year, general biology, embryology, human and comparative osteology, the second year, animal physiology and histology, zoology, and comparative anatomy. The laboratory is daily open for practical instruction in connection with lectures and recitations.

Under the instruction of Professor Martin and his associate, Dr. Brooks, with the advantages of an excellent laboratory, a very extensive and well-selected apparatus, with the stimulus of congenial scientific companionship, and with the temptations of the zoölogical laboratory at Beaufort, N. C., and of its elementary seaside school, one may readily anticipate that preliminary studies will in some instances insensibly glide in the course of time into valuable original work, the university thus getting back in the higher morphological development of a ripe harvest the seed which she is now so trustfully sowing.

MEDICAL NOTES.

— We regret to have to record the death of Dr. R. O. Cowling, of Louisville, the founder and editor of the *Louisville Medical News*, at the early age of forty-two years, from rheumatic endocarditis.

— At a late meeting of the board of overseers of Harvard University, Thomas B. Curtis, M. D., was appointed instructor in the medical school for the current year in diseases of the urinary organs; E. H. Bradford, M. D., in orthopaedic surgery; O. F. Wadsworth, M. D., in ophthalmoscopy.

— We understand that Mr. Spencer Wells has lately operated successfully for the removal of an ovarian tumor from a child seven years of age.

— The daily papers have contained accounts lately of the progress in voluntary starvation of a young woman at the West, who was evidently insane. She remained forty-seven days without food before death released her. The reports seemed more reliable than those of similar sensational occurrences are apt to be.

— The Royal College of Physicians of London is somewhat agitated over the course pursued by Dr. Quain in consulting with Dr. Kidd, a quasi-homoeopathist, in the case of the Earl of Beaconsfield, some account of which is given in a letter, on another page, from our London correspondent. This topic has moved a much-respected daily contemporary to query, "Is there any such thing as a science of medicine? . . . Chemists do not quarrel as to the effects of two substances upon each other, why should doctors disagree, after centuries of recorded experience and study, as to the effects of drugs upon the human system?" etc., etc. — We are considering the wisdom of

offering a prize for an answer which will serve to prevent people from continuing to ask similarly foolish questions.

— Under the head of Physiology for Fools the London *Lancet* thus commences a very interesting note:—

The Rev. Joseph Cook, a well-known American pulpit-orator, has come over to this benighted country to overthrow Huxley, Michael Foster, and other philosophers. The plea for this special mission appears to be that, having himself attained to an accurate knowledge of scientific research, he is competent to expose the fallacies of men of science. Judging, however, from some extraordinary statements which this lecturer is reported to have made with reference to the action of alcohol on the living brain, our modern scientific inquirers may take heart of grace, and rest in peace a little longer.

— Carlyle once rode sixty miles to Edinburgh, "to consult a doctor, having," as he says, "at last reduced my complexities to a single question. Is this disease curable by medicine? or is it chronic, incurable except by regimen, if even so? This question I earnestly put; got response, 'It is all tobacco, sir; give up tobacco.' Gave it instantly and strictly up. Found, after long months, that I might as well have ridden sixty miles in the opposite direction, and poured my sorrows into the long hairy ear of the first jackass I came upon as into this medical man's, whose name I will not mention."

— Milk vendors, it is stated, in the *Sanitary Record*, are in the habit, at present, of largely adding salicylic acid to milk, for the purpose of preventing its turning sour when kept. This addition has recently been prohibited in France by the minister of health, and M. Girard recommends the following tests for revealing the presence of salicylic acid in milk: In one hundred cc. of suspected milk place one hundred cc. of warm water and five drops of acetic acid. Filter to separate the casein, shake the filtered fluid with fifty cc. of ether. Decant the ethereal layer, and evaporate it on a watch-glass. To the residue of evaporation add one per cent. solution of iron; the salicylic acid presents an intense violet color.

— The *Reporter* gives the following interesting decision: Under a marriage settlement the fund was to go to the survivor for life, and then in trust for the children of the marriage, as the husband and wife should appoint, and in default of such appointment for all the children of the wife by her then intended or any future husband equally. The husband died, and but one child was born, who died unmarried and intestate, and the widow did not marry again. After the death of the child, the widow, then fifty years old, applied to have the fund paid over to her, and the trustees presented a petition for advice. The vice-chancellor said: "I do not believe there is an instance known of a woman over fifty-two having a child. I do not think, however often the widow may marry, she will have any more children, and I advise the trustees that they may safely pay the money to her."

PHILADELPHIA.

—There is every indication that the bill creating a State Board of Health will become a law at the present session of the legislature. It is in charge of a committee of the State Medical Society, who seem thoroughly in earnest in the matter, and determined to see it through this time. When it passed to a second reading there were one hundred and thirty-one for and only five votes against the bill. The proposed board is to consist of six persons appointed by the governor, subject to confirmation by the senate. Besides the general supervision of the public health and the conduct of sanitary investigations, it shall superintend the collection of vital statistics, report for legislative action a code of sanitary laws, and presents an annual report to the governor. The board also has the power to pass upon the competency of practitioners of medicine, and to compel registration, and give licenses to practice medicine. The latter authority has an element of danger in it, if the board should ever fall under the control of persons inimical to the regular medical profession.

—There is such a thing as too much legislative interference with medical affairs, as witness two bills now before the legislature, — one requiring all prescriptions to be written in English, and a copy of them pasted upon the outside of the bottle, the other declaring it to be a misdemeanor for a medical society to punish any member for consultation with practitioners of "other schools" of medicine! It is scarcely surprising that a legislature capable of originating and entertaining such bills is slow to see the necessity of having a State Board of Health.

—Hon. Thomas A. Scott, of the Pennsylvania railroad, it is reported, has lately presented fifty thousand dollars each to the University of Pennsylvania and the Jefferson Medical College, and thirty thousand dollars to the Orthopædic Hospital of this city.

—A poor family in this city was made sick last week by eating a ham which had been given to them, and the two younger children, aged one and three years, respectively, died from the effects. It was at first thought that trichiniasis was the explanation, but as no evidence of the parasite was detected the cases were set down as fatal entero-colitis, caused by spoiled meat.

—Ex-Dean Miller is again in trouble, this time on a serious charge. The coroner, Dr. Janney, on the 5th inst., held an inquest upon the body of the infant of a young woman named Mary Butler, employed as a servant in a family. The sworn deposition of the mother accused Dr. I. J. Hathaway with criminal malpractice, and Dr. Thomas B. Miller, formerly connected with the college on North Tenth Street, with being an accessory. Miller and Hathaway were in custody at the inquest. The deposition was read, and the jury, in their verdict, found Hathaway guilty of criminal malpractice, and Miller and another party not arrested accessories before the fact. Miller and Hathaway were committed to await the action of the district attorney.

—The coroner, a few days ago, also held an inquest on a child of three years, who was killed by

overdoses of a patent medicine, the composition of which was unknown to the parents, but it is known to the profession to contain a poisonous proportion of digitalis. Should not proprietors of patented preparations be compelled to publish and affix to each package of medicine the working formula or at least the definite composition of the medicine exposed for public sale?

WASHINGTON.

—On March 17th the medical department of Columbian University held its annual commencement with a class of five graduates, at the same time granting certificates of successful examination in the primary branches to seven undergraduates.

—On March 31st the medical department of the University of Georgetown held its annual commencement with a class of five graduates, at the same time granting certificates of successful examinations in the primary branches to five undergraduates.

—In the Medical Association, D. C., the much-vexed question of the interference of druggists by prescribing over the counter, and renewing prescriptions independently of the wish of the prescriber, has been discussed during two separate meetings, the discussion has found its way into the daily newspapers, and the druggists and their friends have replied through the same medium by the present fashion of interviews. The result has been that very little good has been accomplished, and a good deal of hostile feeling has been engendered. The doctors cannot afford to foster such a feeling of hostility on the part of the druggists, as it will deprive so many of them of an occupation and place of resort, in the corner drug store, which furnishes much of the benefits of a club to them; they will probably continue to send their patients to the druggist, and order the old bottles to be refilled, and time-worn prescriptions to be renewed, as usual, and the druggists will continue to furnish quack medicines, favorite special prescriptions, and to renew medicines at their discretion.

The committee appointed by the Medical Association reported a preamble and set of resolutions, which were adopted. The preamble was carefully worded, and set forth fairly the relations between doctor and druggist; it laid stress upon the fact that many fatal diseases have their commencement in slight and apparently unimportant symptoms, and showed the danger of treating these symptoms at hap-hazard, citing instances where unwarranted renewal of prescriptions had established the opium habit, produced insanity from chloral hydrate (?) and brought on a violent attack of colica pictonum. The resolutions were in themselves of a negative character, except with two clauses: one that prescriptions marked "Not to be renewed" should not be renewed, and the other, that when this is disregarded by druggists the Association should withhold its support and patronage from the offending parties.

The druggists, on their part, raise the cry that young doctors are the only ones interested; undoubtedly they are, but the older men have advised and acted with them. They lay stress upon the pharma-

ceutical knowledge required to compound prescriptions, and claim that but a small proportion of the medical practitioners of the present day possess that knowledge, which is probably very true, but they seem to forget that yearly they themselves are losing this knowledge by receiving and dispensing the preparations of manufacturing houses, which have now almost entire control of the drug market. For example, it has been somewhat difficult for some time past to get a druggist to prepare a fresh quinine pill, uncoated with sugar, gelatine, or what not. So that if the matter should ever come to this final test it would be much easier for the doctors to procure and dispense their own medicines for themselves than for the druggists to show that any pharmaceutical knowledge is necessary for the purpose. A knowledge of weights and measures, and faith in the most reliable drug manufacturers would be all that was requisite.

CHICAGO.

—The commencement of the Chicago Medical College occurred March 29th. Forty-five gentlemen received the degree of doctor of medicine, one of whom received the honorary degree. The address of the occasion was made by Prof. J. H. Hollister. It treated of the history of the college and its work in behalf of medical education. The secretary read a report of the work of the college for the past year. The showing was regarded very favorable for the college. In the evening the faculty entertained the alumni of the college at a banquet at the Tremont House. Previous to the banquet there was a business meeting of the alumni association.

—A competitive examination for internes and externes occurred at the Cook County Hospital, March 31st. In a class of five applicants one was a lady, Miss Bates, a recent graduate of the Woman's College. She won the second position, it being one of the internships. This is the second instance of an application by a woman for such a position at this hospital, and the first instance of her success. The recent examination was, on the part of the class of applicants, the most creditable one that has occurred for several years.

—Dr. Moses Gunn and wife sailed for Europe on the 26th ult. They will be absent six months.

—We are in the midst of an epidemic of *rötheln*. It commenced several weeks ago, and the cases in the aggregate have been quite numerous. Different physicians have characterized it by different names, some calling it a bastard measles, some a mild epidemic of measles, others anomalous measles, and a few by the name *rötheln*, or German measles.

In the average of the cases so far there has been very little initial fever, the rash and catarrhal symptoms appearing almost simultaneously with the fever. The rash resembles that of measles most, while the throat is like that of scarlet fever; the rash remains only two or three days, and with its subsidence the fever departs, but the pharyngitis remains in some cases for a number of days. The patients have neither felt nor appeared very sick, and no complications or sequels have been noted. The patients are of course

mostly children, but a few are adults. In some cases whole families of children have in succession had the disease; in most cases the patients had previously had true measles, and no cases of true measles, so far as the writer knows, have occurred under circumstances that made it even probable that they were induced by the present epidemic of *rötheln*.

—Chicago is getting to be a great medical centre. While Boston can support only one college of regular medicine Chicago has already three, and we are now promised a fourth. It is impossible to say anything definitely of the scheme of the new college, because the writer's knowledge of it is gained by rumor and in fragments. It is safe to say of it, however, that it will be strictly regular and respectable, it will take male students only, and in its organization it will be similar to most of the colleges in this country. It will start out with no new idea or principle for its foundation or platform, and will endeavor to secure a part of the patronage now bestowed upon the existing colleges here.

Miscellany.

LETTER FROM LONDON.

MR. EDITOR,—The present serious illness of the ex-Premier, the Earl of Beaconsfield, formerly Mr. Benjamin Disraeli, who is suffering from an unusually severe asthmatical and gouty attack, is the occasion for much speculative gossip on a question of medical ethics in aristocratic and medical circles. His regular medical attendant for some time past has been Dr. Joseph Kidd, an eminently fashionable practitioner, a Doctor of Medicine of Aberdeen, where he graduated in 1853, and a Member of the Royal College of Surgeons of England, where he took his diploma in 1846. Dr. Kidd displayed considerable ability, and earned no small credit for himself, in the eyes of his professional brethren, by his work in connection with the Irish famine fever; but he has subsequently identified a profession of homoeopathy with his practice, though few would be found to doubt, as indeed it is very generally stated, that he, regardless of the shackles of either homoeopathy or "allopathy," would prescribe whatever appeared in his judgment best calculated to promote the recovery of his patient. However, having identified himself with homoeopathic practitioners in a discussion concerning them and the regular practitioners, a decided obstacle has been thrown in the way of the latter meeting him in consultation. For it would be an obvious incongruity for an "allopath" to pretend to consult with a homoeopath. Therefore it is urged that the only plea upon which such a consultation could be defended would be the very questionable one that Dr. Kidd practiced "allopathically" whilst announcing himself to be a homoeopathic practitioner.

It was commonly thought that Sir William Jenner would decline, if asked, as he very probably might be, to meet Dr. Kidd in this case; for Sir William's very high standard of medical ethics is proverbial, and he is justly looked up to in this respect. To-day's papers announce that Dr. Quain has been in consultation with Dr. Kidd; and if this be true, as doubtless it is, your readers may expect to see some correspondence and comments on the subject in your medical and so-

ciety contemporaries on this side. It was Dr. Kidd who was summoned to attend the Earl of Beaconsfield when he was unwell during his labors at the Berlin conference.

Dr. Whipple and Mr. Pick communicated to the clinical society, last Friday evening, the particulars of the case in which, as I mentioned in a previous letter, the latter performed extirpation of the entire larynx.

The patient, a commercial traveler, aged thirty-nine, has been under Dr. Whipple's observation, for laryngeal troubles, since early in 1876. In June, 1876, a warty growth was seen on the left ventricular cord, and removal of the tumor, by an intra-laryngeal operation, afforded marked relief. The macroscopic and microscopic appearances then alike indicated the thoroughly papillomatous character of the disease, which recurred, and was again similarly removed in February, 1877.

Repeated recurrences and removals of similar new formation occurred. In March, 1879, the ventricular band on the right side was seen to be implicated in the disease, but up to this date there was no external manifestation of the tumor. By June, 1879, however, the growth, which had attained considerable size within the larynx, was indicated outside by a small, painful, hard, tumor over the left ala of the thyroid. At this time, except that it had penetrated the cartilage, the tumor presented all the appearances of benign papillomatous disease.

Tracheotomy was performed on May 1, 1880, for the relief of urgent dyspnoea, and the patient's condition was so much ameliorated by this operation that he was discharged, wearing a tracheotomy tube, and declining to submit to further surgical treatment.

July, 1880, the laryngeal passage was completely blocked by the growth which could be felt externally to extend on the left side below the thyroid cartilage. In November, 1880, during attacks of cough there was occasional bleeding from the growth, and the patient was wasting markedly. Dr. Whipple called attention to the distinctly papillomatous nature of the disease at its onset, to its retention of an entirely benign appearance during three years, and to the rapidity and clinical malignancy of its progress subsequently to the performance of tracheotomy. Mr. Pick stated that it had been his desire to follow up the operation of tracheotomy, after but a brief interval, by thyrotomy, as even at that time a smooth, nodulated, tender mass was prominent on the left ala of the thyroid which was distended. But, when the effects of that mutilation were explained to the patient, relieved by the tracheotomy, he withheld his consent.

Mr. Pick saw the patient again on January 16, 1881, when he was emaciated, and blanched through a recent loss of blood, and the tumor could be recognized as reaching to the cricoid cartilage, but apparently not extending up to the hyoid bone. On this day, the patient having been placed under ether, the tracheotomy opening was enlarged sufficiently to permit of the introduction of Dr. Semon's modified tampon canula, and the ether administration was continued through the tracheotomy tube. The thyrotomy was accomplished through a vertical incision, in the median line, bisected by a horizontal incision. The thyroid cartilage was at once split down the centre of its front, the halves widely separated, and the whole mass exposed to the full extent of its limit. Next, dealing with one side at a time, each half was well drawn forward and severed from its surrounding attachments. The cricoid was similarly

treated. The arytenoid cartilages were removed, as were the epiglottis, which had been invaded by the disease. The tampon canula answered admirably. The entire operation occupied but forty-five minutes, at no time occasioned formidable hemorrhage, and did not demand the application of a single ligature. The patient succumbed on the fifth day apparently from nervous shock.

Mr. Pick strongly advocated splitting the larynx into its lateral halves prior to attempting its extirpation, as thus the risk of wounding the important neighboring structures was greatly diminished, and furthermore an exact knowledge was gained early as to the extent of parts involved in the disease, and therefore demanding removal. The operator pronounced extirpation of the larynx to be an established operation, which, despite the terrible character of the mutilation, should not be too long postponed when definitely malignant disease had invaded the organ; he considered that the case under discussion was one in which that radical proceeding might have been practiced six months earlier with propriety. He quoted some interesting statistics relating to the operation, which had in most instances been performed for carcinoma, mentioning eighteen cases, particulars of which had been recorded by Morrell Mackenzie. Seven of these eighteen died from the immediate effects of the operation, one from a bougie perforating the pericardium, in eight the disease subsequently proved speedily fatal, but the fatal issue had been deferred in two cases of spindle-celled sarcoma.

Dr. Felix Semon, whose modified tampon canula had been used in the operation, at which he was present, bore well-merited testimony to the operative skill displayed on the occasion, saying that to Mr. Pick was due the unobtrusiveness of those difficulties and dangers which so usually crowd around this extreme surgical procedure. Dr. Felix Semon mentioned the importance of neither too rapidly nor too fully inflating the tampon canula, as in either case inconvenient symptoms (arrest of respiration) may result, probably from influences conveyed to the vagus through its tracheal branches. This caution and suggestion he had made two years previously, at a time when it was but little received; however, his subsequent experience, and that which had been communicated to him by others, led him to repeat the hint with greater confidence. He was ardent in urging that the radical measure of extirpation of the larynx, with all its attendant consequences, should be reserved for only such cases as the microscope had shown to be malignant. He quoted a case recently published at Berlin, in which the operation had been recommended and rejected after disease had recurred subsequently to removal through the mouth, but in which the child had been enjoying a long period of exemption from any recurrence of the mischief, after it had been repeatedly removed with the sharp spoon. He urged persistent removals per vias naturales until there was microscopic confirmation of the malignant characters of the parts removed.

IMPORTANT ORIGINAL PHYSIOLOGICAL RESEARCH.

At the meeting of the Royal Society, on Thursday last, Professors Ferrier and Gerald Yeo contributed a most interesting account of the results furnished by some highly important investigations which they had carried out with a view to ascertaining the functions subserved by the plexiform arrangement of the nerves of the limbs, and the mode of distribution of the sev-

eral roots of the brachial and crural plexuses, which afford a subject of considerable physiological and pathological interest.

The authors referred to investigations into the subject by Johannes Müller, Van Deen, Kronenberg, Bartolomeo Panizza, Peyer, and Krause; quoting the experiment, on a monkey, in which the last named found that no degeneration ensued in the ulnar or median sensory nerves of the hand after division of the fifth and sixth cervical nerves; and concluded, by analogy from the ascertained distribution in the rabbit, that the ulnar and median digital nerves were derived from the first dorsal and eighth cervical respectively. Alluding to Erb's discovery, that by faradization over the brachial plexus, at a point corresponding with the exit of the sixth cervical nerve from between the *scaleni* muscles, the *deltoid*, *biceps*, *brachialis*, and *supinator longus* can be thrown into simultaneous contraction; and his statement that at the same time it is difficult to avoid the *musculo-spiral* nerve, which can also, however, be separately excited, the authors had themselves found extension of the wrist constantly accompanying all distinct actions of the above muscular group. From the collocation of the muscles affected in atrophic spinal paralysis, Remak argued that functionally related or synergic muscles are represented together on the anterior horns of the spinal cord.

Professors Ferrier and Yeo have made a series of experiments on the motor roots of the brachial and lumbo-sacral plexuses in monkeys. The brachial plexus in the monkey corresponds closely with that of man. Though the lumbar and sacral plexuses do not at first appear to correspond, owing to there being seven lumbar vertebrae in the monkeys. The authors showed that by reckoning the first and last lumbar vertebrae to be dorsal and sacral respectively, the harmony, as regards the mode of distribution of the several roots, becomes complete; and suggested that it appeared warrantable to make the constitution of the lumbar and sacral plexuses a means of determining to which group the variable dorsal, lumbar, and sacral vertebrae in monkeys should be referred.

The operation was performed when the animals were deeply narcotized. The vertebra over the cervical or lumbar nerves were exposed, and the arches removed so as to expose the cord. The dura mater was opened, and in the case of the cervical and dorsal nerves the posterior roots were cut, to avoid all reflex movements on stimulation. The motor roots were stimulated by closely approximated needle electrodes, by means of the induced current of Du Bois Reymond's secondary coil. Every precaution was taken to insulate the roots, and unavoidable diffusion was more or less eliminated by frequent repetition and uniformity in the results. In observing the effects of stimulation, attention was given more especially to the resultant muscular combination rather than to the mere number of muscles thrown into action. This is of importance, as the actions excited are all complex, coordinated movements of great significance, and it is difficult, where so many events are occurring simultaneously, to analyze each muscular combination into the individual factors at work; therefore the muscles which the authors state to be in action are those collected from various observations.

They had experimented seven times on the brachial plexus, once unsuccessfully, and six times on the lumbo-sacral plexus, twice with but partial success. The resultant actions had been very uniform. The authors

treating of the brachial plexus gave the results afforded by their stimulation of the roots of the first dorsal and eighth to fourth cervical individually. Similarly, in reference to the crural plexus, they recorded action induced by stimulation of the motor roots of the first sacral, seventh, sixth, fifth, and fourth lumbar in the monkey; corresponding, as explained, to the second and first sacral, fifth, fourth, and third lumbar in man. But space will not admit a full account, and justice cannot be done in any condensed report of these intricate and important observations, so I will briefly summarize the result obtained by the stimulation of some single root in either plexus, and leave the reader to form an estimate of the value of the communication which he must wait to peruse in the *Transactions of the Royal Society*.

Stimulation of the motor root of the eighth cervical induced a complex action, comprising firm closure of the fist, flexion of the wrist to the ulnar side, extension of the forearm with retraction of the upper arm, the long head of the *triceps* being especially in action. This complex movement may be exactly imitated by pulling some object hanging in front downwards and towards the hip, or by drawing a scimitar from heel to point through some object lying in front. The muscles involved imply stimulation of nerves converged in the ulnar, median, and *musculo-spiral*. Stimulation of the monkey's fifth lumbar (fourth lumbar in man) induced extension of the thigh, extension of the leg, and pointing of the great toe, with the combined result of straightening the whole limb directly backwards, as in the movement which immediately precedes the lifting of the foot to take another step forward in walking. The muscles observed in action were the *gluteal*, the *adductors*, *extensor cruris*, and the *peroneus longus*. This latter explaining the pointing of the great toe by depression of the base of the first metatarsal bone; and at the same time the raising of the outer edge of the foot. The sacral muscles did not appear to contract. This action involves stimulation of nerves conveyed by the superior *gluteal* obturator and *musculo-cutaneous* branch of the external popliteal nerve.

The movements which resulted from stimulation of the individual roots of the brachial and crural plexuses were not mere contractions, more or less strong, of various muscles, though many muscles were excited to contraction by more than one root, as previous experimenters had found, but a highly coördinated synergy in each case, as Remak supposed.

The muscles thrown into action by each root are innervated in most cases by several nerve-trunks, when it would appear that the plexiform functions of the various roots are for the purpose of distributing the requisite motor fibres in different trunks to the various muscles engaged in each functional combination.

The result of section of each motor root would, therefore, be paralysis of the corresponding combination; not necessarily, however, of the individual muscles involved, for, as many of these are innervated by more than one root, the degree of paralysis of the muscles would depend on the degree of motor innervation by the root divided, and therefore while weakened they might yet act in other combinations in so far as they were supplied by other roots. Such appears to Ferrier and Yeo the real explanation of the fact stated by Panizza, that there was no absolute immobility of the limb in his experiments until every root was cut.

London, March 30, 1881.

A TRIBUTE TO THE LATE SURGEON OTIS.

The following letter from the Surgeon-General of the British Army is circulated by Surgeon-General Barnes, and we take great pleasure in reproducing it. It shows a just appreciation of the talents and services of Dr. Otis.

ARMY MEDICAL SCHOOL, ROYAL VICTORIA }
HOSPITAL, NETLEY, March 30, 1881. }

MY DEAR SIR, — I cannot describe the sorrow I feel at the sad tidings which your circular note of the 25th ultimo has just conveyed to me, nor can I in any adequate manner express my sense of the immense loss surgical science has sustained — especially the science of military surgery — by the death of your indefatigable and talented assistant, Surgeon Otis. Still I feel I must write a few words to say how deeply I sympathize with you, and with all the medical officers under your

direction, in the grievous loss you and they have sustained in the death of so distinguished a member of your corps. Military surgery, and all who are engaged in its practice, in every part of the world, and, I might add, every one who may happen to be in need of military surgical help, owe, under the liberality of the United State Government and your auspices, a debt of gratitude to Surgeon Otis which, though it can never be repaid, will never be forgotten as long as the great surgical history of the War of the Rebellion and his other valuable works exist. It is with perfect truth that you remark the death of Surgeon Otis will be deeply deplored, not only by the members of the medical profession in his own service and country, but also by the medical profession of the whole world. Believe me to be, very dear sir, very faithfully yours,

THOMAS LONGMORE, Surgeon-General.

MAJOR-GENERAL, J. K. BARNES,
Surgeon-General, United States Army.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 9, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 3065; 1074 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 622, consumption 485, lung diseases 426, diphtheria and croup 180, scarlet fever 128, cerebro-spinal meningitis 65, typhoid fever 62, small-pox 49, diarrhoeal diseases 37, measles 33, malarial fevers 26, erysipelas 18, whooping-cough 17, puerperal fever seven. From *typhoid fever*, New York and Philadelphia 12, Pittsburgh six, Lawrence five, Boston and St. Louis four, Holyoke and Newton two, Brooklyn, Chicago, Baltimore, Cincinnati, New Orleans, District of Columbia, Milwaukee, Prov-

idence, New Haven, Charleston, Lowell, Salem, New Bedford, North Adams, and Clinton one. From *small-pox*, Philadelphia 36, New York nine, Chicago three, Pittsburgh one. From *diarrhoeal diseases*, New York 11, New Orleans five, Philadelphia four, Chicago and Baltimore three, Brooklyn, St. Louis, and Cincinnati two, Boston, District of Columbia, Cambridge, New Bedford, and Chelsea one. From *measles*, New York nine, Cincinnati four, Boston and Nashville three, Baltimore, New Orleans, and Providence two, Philadelphia, St. Louis, District of Columbia, Milwaukee, Worcester, Chelsea, Taunton, and Attleborough one. From *malarial fevers*, New York nine, St. Louis

seven, Brooklyn three, District of Columbia two, Chicago, Baltimore, Milwaukee, Nashville, and Holyoke one. From *erysipelas*, New York eight, Brooklyn and Chicago two, Boston, Baltimore, Milwaukee, Providence, Charleston, and Newton one. From *whooping-cough*, New York four, Philadelphia three, Brooklyn two, St. Louis, Baltimore, Cincinnati, Pittsburgh, Providence, Worcester, and New Bedford one. From *puerperal fever*, Chicago three, St. Louis two, Philadelphia and Holyoke, one. The mortality from cerebro-spinal meningitis has decreased from 80 for the week ending April 2d to 65.

Twelve cases of small-pox were reported in Brooklyn, 18 in Chicago, four in Pittsburgh, and one in Milwaukee; diphtheria 36, scarlet fever nine in Boston; scarlet fever 20, diphtheria 11, in Milwaukee.

In 45 cities and towns of Massachusetts, with a population of 1,120,087 (population of the State 1,783,086), the total death-rate for the week was 24.16, against 20.71 and 22.20 for the previous two weeks.

For the week ending March 19th, in 149 German cities and towns, with an estimated population of 7,639,529, the death-rate was 27. Deaths reported 3968; 1859 under five: pulmonary consumption 601, acute diseases of the respiratory organs 436, croup and diphtheria 155, diarrhoeal diseases 134, scarlet fever 79, typhoid fever 48, measles and *rötheln* 47, whooping-cough 43, puerperal fever 36, small-pox (Königsberg four, Lü-

beck, Berlin four, Aachen four) 13, typhus fever (Elbing, Stutgard five, Posen two, Dessau) nine. The death-rates ranged from 16.3 in Potsdam to 46.3 in Erfurt; Königsberg 26.5; Breslau 41.3; Munich 30.7; Dresden 26; Berlin 23.1; Leipzig 23.4; Hamburg 28.1; Hanover 21.6; Bremen 23.6; Cologne 36; Frankfurt 19.7.

For the week ending March 26th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 21.7. Deaths reported 3163; acute diseases of the respiratory organs 348, whooping-cough 78, scarlet fever 56, measles 55, small-pox (London 49) 51, fever 37, diarrhoea 27, diphtheria 17. The death-rates ranged from 17.2 in Salford to 28.1 in Liverpool; Birmingham 18; Sheffield 20; Bristol 20.4; London 21.3; Manchester 21.9; Leeds 25. In Edinburgh 24.3; Glasgow 24; Dublin 34.9.

In the 20 chief towns in Switzerland, for the week ending March 26th, population 548,301, there were 39 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 20, typhoid fever 11, diphtheria and croup nine, measles five, puerperal fever two, small-pox one. The death-rate of Geneva was 22.8, Zurich 34.5, Basle 34.5, Berne 37.7.

ERRATUM. In the report of English cities last week, for small-pox (London 13) read (London 43).

The meteorological record for the week in Boston was as follows:—

Date.		Barometer.		Thermometer.		Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 9, 1881, TO APRIL 15, 1881.

COOPER, GEORGE E., lieutenant-colonel and assistant medical purveyor. Died at San Francisco, Cal., April 13, 1881.

CORRECTION.

MR. EDITOR.—A slight error in the secretary's abstract of the paper read by me before the Suffolk District Medical Society, printed in the issue of your journal, April 14th, injures the sense very materially. The passage in question reads: "Time alone seems to furnish all remedies for disease in the body;" it should read "in this body," "this" referring to the faculty, to which body no reform remedy other than that which time itself has furnished has ever been applied.

Very respectfully yours, DAVID HUNT, M. D.
Boston, April 16, 1881.

GYNÆCOLOGICAL SOCIETY OF BOSTON.—The next regular meeting is appointed for the second Thursday of May, — to accommodate gentlemen who may wish to go to Richmond, — at 10.30 o'clock. Paper by H. O. Marcy, M. D., on Abdominal Surgery. Profession invited.

HENRY M. FIELD, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED.—On the Antagonism between Medicines and between Remedies and Diseases, being the Cartwright Lectures for the Year 1880. By Roberts Bartholow, M. D. New York: D. Appleton & Co. 1881.

Anatomical Plates, arranged as a Companion Volume for The Essentials of Anatomy, and for all works upon Descriptive Anatomy, comprising Four Hundred and Thirty-nine Designs on Steel by Professor J. N. Masse, of Paris, and numerous Diagrammatic Cuts selected or designed by the Editor, together with Explanatory Letterpress. Edited by Ambrose L. Ranney, M. D. New York: G. P. Putnam's Sons. 1881.

Lectures.

CLINICAL LECTURE ON SUBACUTE PELVIC PERITONITIS.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

BY PROFESSOR T. GAILLARD THOMAS, M. D.

GENTLEMEN, — The patient now before you presents, I think, a condition of more than ordinary interest. Her name is Esther J—, and she is a native of Poland. She is thirty-nine years of age, is married, and has had ten children and two miscarriages. The last pregnancy resulted in an abortion, and this occurred five months ago. I think you will all be struck with the fact that she looks like a very ill woman, and so much was I impressed with the appearance of her countenance when I first saw her that I at once made a diagnosis of the case in my mind. This was subsequently proved, I may remark, however, to be entirely incorrect. On further questioning, she told me that she had been ill for five months, or, in other words, ever since the miscarriage just mentioned. Up to the time of the latter she says she was perfectly well, and, therefore, it would seem that her present trouble had some connection with this miscarriage. There has never been any period since the miscarriage, she says, when she has felt well. When asked in what way she has been suffering, she states that she feels very weak and has no appetite. She also has some pain, which she says is "almost all over her." This pain is considerably aggravated when she has a passage of the bowels, but at other times does not seem to be at all severe. Her monthly sickness is regular in its occurrence and normal in character, and she has a great deal of leucorrhœal discharge.

You must have noticed, gentlemen, how trivial the symptoms complained of in this case are, with the exception, perhaps, of the leucorrhœa which has just been referred to. When summed up, they consist merely in a loss of appetite and strength, and a little pain when the patient has an evacuation of the bowels. And yet, if we may judge at all from her appearance, there must be something pretty serious the matter with her. If any one of you were called upon to make a diagnosis from what has thus far been elicited in the case, you would very naturally be somewhat puzzled in regard to it. You might, perhaps, suppose that the woman was suffering from fissure of the anus or hæmorrhoids, which frequently give rise to the most intense suffering when the bowels are moved. Or, very likely you would imagine that she was affected by malignant disease, as, indeed, I did when I first looked at her.

Phthisis, Bright's disease, malaria, might all, perhaps, suggest themselves to you; but we find that she has no indication of either one of these. Yet, as I said before, there is evidently something seriously wrong with the patient, and it is therefore highly important that we should find out, if possible, what it is. We are justified in excluding the above affections, and must accordingly look elsewhere for the trouble. Now the patient has told us that she has been suffering from a very profuse leucorrhœa, and since this is the case, we should be culpable if we did not resort to an examination of the pelvic organs, especially as she has also told us that all her trouble dates from a miscarriage which she had a few months ago.

Let me now tell you what was found when the exploration was made. In the first place, the uterus was ascertained to be in its normal position; but instead of being freely movable, as it should have been, I found it perfectly fixed. When the finger was passed behind the cervix it met everywhere with a firm, resisting surface, for Douglas's sac and the whole roof of the pelvis were like a hard board. If you were to open the abdomen of a cadaver and pour down into the pelvis a quantity of plaster of Paris, and then, having allowed it to "set," should make an examination *per vaginam*, you would get precisely the sensation that is met with by the exploring finger in this case. The only movable part here is the bladder; and this, from the nature of circumstances, is always more or less movable, whatever may be the condition of the other organs, even when there has been an inflammatory process going on between the bladder and the anterior vaginal wall. In addition, I found that the vagina was filled with ichorous leucorrhœal material, which had caused marked irritation of all the parts with which it came in contact, including even the thighs of the patient.

There is but one affection that could produce such a state of affairs as has just been described to you, and that is pelvic peritonitis. It is, as you are no doubt aware, very frequently conjoined with pelvic cellulitis; and many would have you believe that we are only "splitting hairs" in trying to make a distinction between them. But I hold that it is just as philosophical to distinguish between the two as it is between pneumonia and pleurisy. Of course, it is possible to have pneumonia without pleurisy; but *post-mortem* records show conclusively that, as a rule, the latter disease is associated with the former. Yet no one thinks of confounding these, and, as a fact, pleurisy very often occurs independently of pneumonia. So here I can find no evidence that there has been any pelvic cellulitis whatever; while, on the other hand, a fortnight ago I saw what was undoubtedly a perfectly uncomplicated case of pelvic cellulitis, without any peritonitis. If we want to understand these two disorders properly it is necessary that we should study them separately. As long as the term *carditis* was used to express all the inflammatory affections of the heart very little was known about the subject; but when *endo-carditis* and *peri-carditis* began to be investigated separately a great deal of light was at once thrown upon it, and a correct and definite idea of it was for the first time obtainable.

I dwell upon this case at some little length because it is a typical one of chronic pelvic peritonitis, of the adynamic or asthenic type, as the old writers would call it. It has crept on very insidiously, and on this account has not presented the typical symptoms of the affection. All the local trouble to which it has given rise, apparently, is this ichorous leucorrhœa and some constriction of the rectum. In the same way Bright's disease often exists for a long time without even being suspected, and pleurisy may go on for months unnoticed; the presence of a little fever and quickened respiration, with the occurrence of night-sweats, perhaps, at last calling attention to the condition of the chest. I have not the slightest doubt of the diagnosis in this case, for the state of affairs that has been ascertained to be present in the pelvis is quite sufficient to account for the failure of the patient's general health, which has been noted. Before speaking of the prognosis and treatment, I wish to throw out a single point

in regard to the differential diagnosis so far as carcinoma is concerned. On feeling the board-like tissues here, an inexperienced examiner would probably think that he had a malignant growth to deal with, on account of their extreme hardness. But it is important to remember that such growths are very rare indeed in this position, and that when they do occur, they are found in distinct masses, and not generally disseminated, like this inflammatory material.

As to the prognosis, I believe that this patient will get entirely well. Mark you, that I do not say that she can be *cured*; for there is no medicine whatever with which I am acquainted that is capable of curing pelvic peritonitis. I wish that I could impress upon each one of you that hears me to-day the idea that drugs should be thought of *last* when we are considering the agencies that may be of service to any patient that is placed in our hands for treatment. It is true that we have specifics for syphilis, malaria, and ulcerative stomatitis, and almost a specific for epilepsy; but these are all the affections for which for we have any, and when we pass beyond them we can employ medicines only as adjuncts to other means of treatment. It may perhaps be thought that counter-irritation may accomplish a good deal here; but I do not believe that it will be of much service. Still, it is, at all events, worth while to try it, and I should recommend that the whole roof of the pelvis should be painted over with iodine about once a week.

The most important element now in the case is the general depreciation of the patient's condition, and this we must endeavor to contend against. She should, therefore, be at once put upon the bitter tonics, not for the purpose of curing the peritonitis, but in order to give her an appetite, so that she may take such food as will tend to build up her constitution. As her blood is no doubt in a very poor condition, she should eat an increased amount of food, and I think it would therefore be advisable for her to take not only the three ordinary meals, but something between these also; such as eggs, milk, farinaceous gruels, or anything that you please which will afford her nourishment. Besides, I would place her on such tonics as iron and the hypophosphites, as articles of diet; and I think that even within ten days there would be an appreciable improvement in her condition. It is very important that such a patient as this should be entirely free from care and should not be required to perform any physical or mental labor. Enough has been said, I think, to show you how little we can depend on medicines in such a case as this; but if the plan which I have suggested is adopted, I do not doubt that the inflammation here present, which is of a very low grade, will entirely disappear in time. At all events, it will prove of some service to this good woman to know just what is the matter with her; for she has already consulted a number of physicians, and each of them, it would seem, has made a different diagnosis.

— Sir William Jenner, M. D., K. C. B., has been elected president of the Royal College of Physicians of London. He is, it is stated, the first president of the College of Physicians who has received a license to practice from all the English medical corporations, namely, the College of Physicians, the College of Surgeons, and the Society of Apothecaries. He is also the first graduate of the University of London who has been elected president of the College of Physicians.

SO-CALLED CONCUSSION OF THE SPINAL CORD.¹

BY R. M. HODGES, M. D.

What we know in regard to recovery from organic affections of the spinal cord; of the extent to which Pott's disease, and the atrophied cord left behind, admit of restoration; and of the gradual but complete cure of myelitis, by no means justifies the conclusion ordinarily reached as to the inevitable consequences of serious medullary lesions.² Still more true is it that the prognosis in litigation cases where the so-called symptoms of concussion of the spinal cord are set forth, is far better than is generally supposed, or alleged in evidence. An eminent lawyer, than whom no one, in this community, has had larger experience as counsel for the plaintiff in law suits where this condition has been assumed to exist, is said to have remarked that "he should like to see a case of 'concussion of the spine' which did not ultimately get well." Oré and Poinsolet declare that however severe the immediate results, it is rare for concussion to endanger life. "When it appears with the train of symptoms which properly belongs to it, it is, of all the injuries of the spinal cord, the one which offers the least serious prognosis. Their aggravation after a temporary lull is not a wholly unfavorable indication, for this may be due to that subsequent congestion which Lendet³ has described, and which yields without much delay."⁴

Of twelve cases of concussion of the spinal cord, comprising all that are reported in the History of the War of the Rebellion, eight returned to duty; three were discharged from the service; and one died of "chronic peritonitis," an accidental and irrelevant complication.

I have traced the subsequent history of twenty-one litigation cases (already alluded to), of which I have the notes. None of them occurred more recently than 1876. Of these twenty-one cases twelve have recovered, and six claim to have only partially recovered. In three no improvement has taken place.

Two hundred and forty-one persons were injured in the Wollaston accident, October 8, 1878, and their individual claims against the Old Colony Railroad Company were settled by the payment of either a large or a small sum of money. The records of these cases, through the courtesy of the officers of the company and of D. G. Lovejoy, M. D., its medical adviser, have been placed in my hands for examination. Fifty-three were considered as fairly to be accounted subjects of so-called symptoms of concussion of the spinal cord. This conclusion was arrived at either by myself after personal interviews with the claimants themselves; or from a study of the reports rendered by physicians; or it was the definite diagnosis given by the medical attendant or consultant. I have included in this enumeration no case where it did not seem to me that the condition asserted to exist could be maintained with an amount of evidence which might influence a jury of non-professional men in a belief of its reality. Of these fifty-three cases there were but three in which there was

⁴ Nouv. Dict. de Méd. et de Chir., Tome 22, page 810.

uniformity of opinion as to the actual condition of the claimant on the part of the physicians who examined them. Twelve cases were distinctly and openly fraudulent, and of the whole number there were but two the subjects of which, fifteen months after the accident, had not recovered from the symptoms presented by them at the time the settlement was made. Nineteen of the fifty-three were paid \$1000. and upwards. These latter might consequently be presumed to be the more conclusive and positive instances of the condition claimed to exist; and yet recovery was equally rapid whether a large or small award was made. No one of these fifty-three cases was brought to a jury trial. In twenty the award was made by a board of arbitration. In all but four instances this board was composed of three physicians, and in only one was there no physician.

In the Wollaston accident there were twelve hundred persons on the train at the time of its derailment. Thirteen persons were killed outright, and more than two hundred and fifty injured, of whom six subsequently died. It is impossible to determine how many cases of claims preferred were absolutely fraudulent or grossly exaggerated in their character. It is a notorious fact that this was true of a large number. Persons claimed compensation for injuries who were not even on the train to which the accident occurred. Attempts were made to palm off old fractures, old hernia, hydroceles, varicoceles, and varicose veins of long standing, as immediate results of the catastrophe. And in several instances boards of arbitration met, counsel were present, claimants examined, and no award made, simply because nothing could be found on which to base any just foundation for the damages demanded.

The striking feature of the accident, looked at pathologically, was the number of persons who claimed to have spat blood, or to have passed it by the bowels, in whom no distinct signs of injury, such as external marks of contusion, fractured ribs, etc., could be found. Of the minor injuries a very large number were due to cuts by broken glass.

Forty-seven persons were paid one thousand dollars or over up to eleven thousand dollars, ninety-seven were paid one hundred dollars or over up to one thousand dollars, and eighty-six were paid one hundred dollars and under. It is estimated that more than twenty-five thousand dollars were paid to physicians for professional services rendered.

The question of medical treatment hardly comes within the scope of this paper. It may be said, with emphasis, however, that in all cases where the so-called symptoms of concussion of the spinal cord are presented, and in which a demand for indemnity is made, no remedy equals an adjustment of the claim for damages. Until this result has been reached therapeutic measures are of little or no service. The curative effect of a pecuniary settlement shows itself more and more conspicuously with every case in which the facts are made known. So long as this issue is undetermined recovery must not be looked for. Attended by one or more physicians, who are constantly directing the patient's attention to his symptoms, visited by others who, perhaps, do not hide their disbelief of his statements, awaiting in trepidation the ordeal of a trial where the seriousness of his alleged illness is to be vigorously contested, brooding over his condition, and unable to occupy his mind in any healthy or active manner, the claimant is placed in the very position which medical advice would counsel him to avoid, and delivery from which cannot but stimulate his efforts to secure health, and promote his chances of regaining it, just as by long continuance of the situation they must be indefinitely postponed.¹

The following notable case, reported more fully in the *Boston Medical and Surgical Journal*, February 12, 1880, is not without interest in connection with the above remarks. —

¹ *Lancet*, March 30, 1867, page 389.

C. W. H., October 15, 1877, received a railroad injury, causing instant paralysis below the waist, with loss of control of both bladder and anus. Pain at the point of injury was incessant, and severe beyond description. After ten weeks there was some return of sensation, and at the end of a year the limbs could be drawn up and pushed down in bed, and even be made to move in walking, with the body supported on crutches and by an attendant. This partial recovery of motility was subsequently lost, and the muscles responded to the action of electricity no more than those of a dead man. In the autumn of 1879, in a suit against the railroad, C. W. H. was awarded heavy damages. On November 30, 1879, he was encased in a plaster jacket. Up to that day "he had not been able to walk a single step, or even to stand without powerful support." Three days afterwards he could walk about his room, and two days later he took his first walk in the street for more than two years; sensation was restored, complete control of the bladder was obtained, and the limbs became as warm as other parts of the body. On the ninth day he "walked a distance of half a mile, and ascended a long spiral staircase." There had been great difficulty in applying the jacket on account of the extreme obesity which had developed during the patient's period of inactivity, and on January 13, 1880, it was replaced by another and better fitting one. On account of the great muscular strength of his arms C. W. H. held himself suspended for forty minutes while the plaster of the second jacket was "setting," and he thus greatly aided in its adjustment. On completion of the apparatus he expressed himself as entirely freed from pain, and he walked with the greatest ease. There appeared to be no paralysis of any muscle, and on February 1st he could raise himself on his toes by the voluntary contraction of the muscles of the leg. Soon after this date C. W. H. went to California.

The question is often asked whether some special legislation is not demanded by the great interests at stake in connection with injuries which so often involve the culpability of individuals and corporations held responsible for their occurrence.

In a certain case, where the so-called symptoms of concussion of the spinal cord were wholly recovered from after settlement by the payment of \$10,000, the plaintiff had been injured by the collapse of a country bridge which she was crossing with a party of friends while on her way home from a picnic. The various persons hurt on this occasion recovered from the little town in which the accident took place a sum said to be one fifth of its assessed valuation. This and similar verdicts led the legislature of Massachusetts to enact a law by which no more than \$4000 can be obtained in judgment from towns for injuries occasioned by defective highways.²

The "Revere accident" cost the Eastern Railroad Company \$500,000, and the "Wollaston accident" is said to have cost the Old Colony Railroad Company more than \$395,000. The total sum paid as compensation for personal injuries by the railways of Great Britain, for the five years 1867-71, was £2,200,000.³

There can be no doubt that these great disbursements, unreasonably increased by exactions strongly impregnated with exaggeration, if not actually fraudulent, constitute an investment by which the community is the recipient, at the expense of railroad corporations, of a constantly increasing dividend in the shape of enhanced security of travel. The "Revere accident," in 1871, was in this way a great public service. "During the seven years succeeding it," says Mr. Charles Francis Adams, Jr.,⁴ "more than once, and on more than one road, accidents occurred which, but for the improved appliances introduced in consequence of the experience at Revere, could hardly have failed of fatal results." In Great Britain "the percentage of casualties to passengers shows a decided tendency to decrease. During the years 1877 and 1878 the percentage of killed fell from one in 15,000,000 to one in 33,000,000, and of injured from one in 436,000 to one in 766,000." In 1879, if the "Tay Bridge dis-

⁴ Notes on Railroad Accidents, page 156.

aster" were excluded from the computation, the proportion of the killed would be less than in any year on record.

The extravagant estimate of the money value of being "shaken," as it is called in England, is largely due in this country at least to a single work, the only one in our language which enters into a detailed discussion of the so-called symptoms of concussion of the spinal cord. It is universally thought to present the subject in stronger colors than it deserves; to show an undue partiality for the public, and to be altogether too severe on the railroad companies. As the literature of the topic is limited, lawyers and physicians naturally refer to this work, and the professional eminence of its distinguished author is legitimately quoted in justification of his statements. Yet the remark has been made that "treatises based, like Mr. Erichsen's, upon the evidence of litigation cases are certainly the last sources of information from which one may learn to make a correct diagnosis and prognosis, and to escape being deceived by the voluntary and involuntary exaggeration and simulation so commonly observed in plaintiffs seeking damages."¹

In Great Britain railroad damages far exceed in individual cases those which are given in the United States. The recent and somewhat famous "Phillips case" is an instance.

The plaintiff, a well-known London physician, claimed that he had a practice worth \$35,000 (£7000)² per annum (an average of three years' receipts), until, in a collision on the Great Northern Railway, he received a severe concussion of the spine, which, the testimony of experts said, would prevent him from ever resuming his professional duties. The jury, largely influenced by the fact that the plaintiff had a private income of £15,000 (£3000) independent of his profession, awarded him \$35,000 (£7000). These damages were thought to be inadequate, and an appeal was made to a higher court. Tried a second time before the Lord Chief Justice and a special jury the sum of \$80,000 (£16,000) was awarded. The defendant railway then claimed that the amount was excessive, and asked for a third trial. The court (Lord Coleridge) stated that "he was not dissatisfied with the verdict," but should refuse the request on technical grounds.

There was reason to think that this case would be carried before Parliament, in order to obtain some rule in regard to the amount of damages to be awarded in similar instances in the future.³

The impartial interests of individuals or corporations, as regards cases in which the so-called symptoms of concussion of the spinal cord are made the subject of a claim for pecuniary damages, can never be reached so long as the present method of enlightening juries and referees in regard to them is maintained.

A joint committee of the Massachusetts Medical Society and of the American Academy of Arts and Sciences, after long deliberation, presented to the legislature of Massachusetts, session 1878-9, the following draft of a law in regard to expert testimony, drawn by the late Hon. Emory Washburn. It was referred to the judiciary committee, but never came to light afterwards.

"When a cause at issue in any court, in which issue is involved any question of art, skill or science, which may in the judgment of the court render it necessary or desirable to examine experts as witnesses in the trial thereof, the court may, in their discretion, appoint and require the attendance of one or more persons to be examined as such experts, and it may allow to such person or persons such sum or sums for fees as witnesses as to said court may seem reasonable and proper, to be charged and allowed as costs to the prevailing party, if he shall have paid the same, unless the court, for good cause, shall otherwise determine. And the court may in their discretion require of the parties, or either of them, to advance and pay to the per-

son or persons thus appointed all or any part of the sum or sums so allowed, before the trial of any such issue be begun or proceeded with."⁴

How is a jury, special though it may be, to determine the value of medical evidence on intricate points of pathology? "The truth is," said Mr. Syme,⁵ "that when juries find the medical evidence so conflicting, not being able to judge for themselves as to the merits of the case, they almost always decide in favor of the claimant, so that there is great encouragement afforded to unfounded or exaggerated demand for redress. Indeed, any man who travels by railway may easily obtain a competency by stumbling on the platform after the door of his carriage has been opened by a servant of the company, but before the train has ceased to move. He has then merely to go to bed, call in a couple of sympathizing doctors, diligently peruse Mr. Erichsen's lately-published work on Railway Injuries, go into court on crutches, and give a doleful account of the distress experienced by his wife and children through his personal sufferings, which have resulted from the culpable negligence that allowed him to leave his seat prematurely. Who can doubt that in such circumstances the jury would give large damages?"

This graphic description shows why attendance in court as an expert is so often an annoying and humiliating experience, and generally avoided by those who are, perhaps, most competent to give evidence. The "side" which summons is constantly spoken of. An expert should not care by whom he is summoned, no matter how strong his convictions, or what his opinions may be in regard to questions in dispute. As a rule, counsel are indifferent whether an honest and skilled witness is called by the plaintiff or defendant. Indeed, a sharp rivalry is often displayed in the attempt to make their opponent's issue a subpoena, and assume the expense of the expert's fee, the non-paying party being quite content with the use of the witness in cross-examination.

The authority of an opinion given by Judge Sprague, December 14, 1854, has never been qualified by any subsequent decision. It is to the effect that "the court will not compel the attendance of an interpreter or expert who has neglected to obey a subpoena, except in case of necessity." This opinion was given on a motion for a writ to compel an interpreter to appear in response to a subpoena which he had refused to obey, and is justified in the following terms: "When a person has knowledge of any fact pertinent to an issue to be tried, he may be compelled to attend as a witness. In this all stand on equal ground. But to compel a person to attend merely because he is accomplished in a particular science, art, or profession, would subject the same individual to be called upon in every case in which any question in his department of knowledge is to be solved. Thus the most eminent physician might be compelled, merely for the ordinary witness fees, to attend from the remotest part of the district, and give his opinion in every trial in which a medical question arose. This is so unreasonable that nothing but necessity can justify it."⁶

With this decision in mind it is the practice of some lawyers never to summon medical experts by subpoena, but simply to request their attendance.

The legislation demanded involves a plan by which the parties interested shall mutually agree to place the settlement of their dispute, so far at least as it is a medical question, in the hands of a board of referees, chosen from accomplished, fair-minded, and disinterested physicians, those of the plaintiff or defendant under no circumstances being of the number, but always appearing as witnesses. Or, if one or perhaps two experts, of known honor and skill, should be designated by the court to visit the plaintiff, without the presence of the counsel on either side, in company with the attending physician, for the purpose of draw-

¹ Boston Medical and Surgical Journal, February 5, 1880.

² In this country evidence as to income, of necessity, an uncertain and fluctuating sum, is not admissible as bearing upon the amount of damages to be awarded, though it may be introduced to show the capacity to earn money possessed by the injured person.

ing up a written report, in simple language, giving their view of the causes, nature, and probable consequences of his condition, present and to come, this report to be a full and final statement of the case for the information of the court, the counsel, and the jury, and to be the common property of all, then even-handed justice may be looked for in investigations, which, as now conducted, are often believed to be characterized by imposition; and the professional discredit which has its origin in the wrangles and contradictions, as well as in the ignorance and conceit, of lawyers and self-styled experts, will vanish in the clearer light by which the controversy will be illuminated.¹

In recapitulation of the preceding pages the following conclusions are presented:—

(1.) The designation, "concussion of the spine," is a misnomer, which has led to the error of considering concussion a disease instead of the cause or traumatic agency of a disease. This objection is removed by substituting for the above term the descriptive title, "symptoms following concussion of the spinal cord."

(2.) Although the shaking occasioned by railroad accidents and collisions constitutes the most frequent cause of their manifestation, various other traumatic influences, with or without an accompanying jar, are followed by the so called symptoms of concussion of the spinal cord.

(3.) Although we are ignorant of the precise pathological changes provoked by concussion of the spinal cord, it is recognized as a cause of organic medullary lesion, which displays itself by symptoms varying in severity from those which are rapidly fatal, to those which are hardly perceptible. It is also a cause of symptoms entirely functional or subjective, which are unaccompanied by any features capable of verification by medical skill, and which are often subject to the volitional control of the patient.

(4.) The symptoms of actual organic changes in the spinal cord, when they follow concussion, are by no means vague and obscure manifestations. They are objective, and admit of recognition and appreciation, being identical with those of idiopathic origin. They are incapable of being simulated with an accuracy which will permit of long deception.

(5.) The subjective symptoms following alleged concussion of the spinal cord are ill defined, vary in degree and character, are such as permit of ready simulation, and but rarely find a counterpart in cases which occur independently of accident or injury, or where motives for deception do not exist. If objective and subjective symptoms are both present in any one case, as not infrequently happens, the objective symptoms predominate.

(6.) The cases which present exclusively subjective symptoms, attributed to concussion of the spinal cord, constitute a distinct class, and owe their peculiarities in a large majority of instances, if not always, to influences growing out of the anticipated or actual litigation, involving claims for pecuniary damages, which so constantly attend them.

(7.) The prognosis of cases in which so-called symptoms of concussion of the spinal cord are developed, is better than has been generally supposed; and in those accompanied by subjective symptoms only is invariably a favorable one as regards ultimate recovery.

(8.) Recovery, or improvement of a fixed and per-

manent character, never takes place until after the adjustment of any existing claim for compensation; and, so long as this is final it makes little difference whether the settlement is a favorable or unfavorable one for the claimant.

(9.) The frequency with which exaggerated and fraudulent cases, presenting the so-called symptoms of concussion of the spinal cord, are made the subject of litigation and claims for pecuniary compensation, will be diminished by legislation providing for a wiser and more discriminating use of "expert" testimony than now prevails.

UNNECESSARY SURGICAL OPERATIONS IN THE TREATMENT OF THE DISEASES OF WOMEN.²

BY CLIFTON E. WING, M. D., BOSTON.

THAT there exists, at the present time, among those who practice the treatment of the diseases of women, too great a love for operative procedures, is an opinion frequently heard expressed by members of the medical profession. These statements are usually answered by the specialists with such remarks as "This specialty is a modern development, and physicians who have not given particular study to these troubles know little or nothing about them or their proper treatment." There is an amount of truth in such an answer which gives it weight; but, still, in this way the question is avoided rather than met. I have stated in a previous article³ my belief that the operative part of the specialty is overdone. Having been repeatedly asked what operations were referred to I will call attention, in the present paper, to some of those most in vogue.

The fees which a gynæcologist can collect for the performance of anything which can be called "a surgical operation" are much greater than the amounts ordinarily earned in the honest treatment of cases by other and simpler means. Unscrupulous practitioners can much increase their incomes by doing as many "surgical operations" as possible. But with two practitioners, equally honorable, and each above a suspicion of sacrificing honesty to pocket, given the same number of similar cases, one will perform more surgical operations in their treatment than will the other. Much depends upon the physician's order of mind, and, perhaps, quite as much upon his early instruction on the subject and the character and practices of those who were his teachers and early associates.

While in the first years of the development of the specialty it was important that the profession should learn that there were certain surgical operations which would afford relief,—oftentimes in cases previously considered incurable,—yet, I think, that at the present time the pendulum has swung far to the other side and that eventually we shall look back upon the present "operative era" in gynæcology with somewhat the same feelings with which we now look back upon the time when all vesico-vaginal fistula were considered incurable, and women who were so unlucky as to have backaches from displaced wombs were blistered and canterized along the back for "spinal trouble."

It has occurred to me that there is an analogy between

² Read at the meeting of the Norfolk District Medical Society, March 22, 1881.

³ Modern Abuse of Gynæcology, read before the Suffolk District Medical Society, April 10, 1880.

¹ Medical Times and Gazette, vol. i., 1869, p. 466. Brit. and For. Med. Chir. Rev., January, 1876, p. 18.

the present practice of many who treat female troubles and some of the orthopaedic practice witnessed in my student days. We used to hear much about the proper method of excising the head of the thigh-bone in hip-joint disease; but little or nothing of value was ever told us about the methods of treating such troubles to prevent the advance of the affection to that stage where excision was a necessity, and the interest excited in our minds over the operation of excision was certainly as great as our interest in the welfare of the poor patients. Few of the students, the operations once through with, thought any more about the cases or ever knew much about the final condition of the patients.

I do not intend to consider in this paper the rare and exceptional gynecological procedures. The operations to which I shall ask attention are some of those most frequently performed, namely:—

- (1.) The Operation for Ruptured Perinaum.
- (2.) Division of the Neck of the Womb.
- (3.) The Operation for Restoring the Neck of the Womb where this has been torn. (Emmett's operation.)
- (4.) Curetting of the Uterine Cavity.
- (5.) The Operation upon the Anterior Vaginal Wall for Prolapse of this Portion and Cystocele.

I have purposely avoided the use of the several long and complex names, troublesome to pronounce and difficult to remember, which have been invented for these procedures. They are only confusing.

RUPTURE OF THE PERINEUM: THE CONDITION NOT ALWAYS AN INDICATION FOR OPERATIVE INTERFERENCE.

Extremes meet in medicine as elsewhere. This fact is exemplified by the difference in the views held by physicians regarding the lesion in question. Some (usually practitioners well advanced in years), are disposed to consider the injury of little or no importance unless, perchance, the rupture is very extensive, involving, perhaps, the sphincter muscle and the rectum; while the most enthusiastic of those holding the opposite opinion tell us that "not a line" of the integrity of the part can be destroyed in labor without disastrous consequences to the woman, and advocate the operation for restoration whenever an opportunity for its performance offers. The accurate clinical observer learns from experience that, as is often the case where opposite views come in contact, the truth lies in a mean between the two extremes.

While the better knowledge of uterine affections which has come to prevail in late years has taught us that the perinaum (or, more properly, the "perineal body") is an important aid to the proper support of the pelvic contents, and that where it is destroyed or greatly injured, the woman usually, sooner or later, suffers more or less inconvenience; yet I question if those who take the extreme view of the matter and assert that every rupture, even if it is only a slight one, is followed by serious results, are not really doing much to retard the recognition of the true importance of the lesion. Practitioners of long experience, who know of instances of laceration of the perinaum, suffered years before, that are unaccompanied by troublesome symptoms, hearing such statements, will be apt to have their confidence in modern gynecology somewhat shaken. On the other hand, young practitioners, with less practical experience, having patients with

uterine symptoms, and finding, on examination, more or less rupture of the perinaum, may easily attribute too much importance to this condition, and overlook other troubles which are present. In a paper published some years ago¹ I called attention to the fact that physicians making a uterine examination, and finding what they had been erroneously taught to regard as "ulceration" at the neck of the womb, were apt to attribute all the patient's pains and aches to this condition, when really it was often of little or no importance, and therefore often failed to look further and detect the real cause or causes of discomfort. Some such caution regarding Rupture of the Perinaum, it seems to me, will not be out of place at the present time, when so much attention is being given to the subject.

I cannot but think that the evils attributed to *slight lacerations* have been greatly exaggerated. It is the exception, and not the rule, to find in women who have borne children a perinaum perfectly intact, and it is a mistake to take as a fixed standard of what every perinaum should be that condition found in nullipara and virgins. Not only are the parts more relaxed and patulous as the result of the distension in child-bearing, but, as Matthews Duncan has pointed out, there is invariably more or less rupture of the vaginal outlet during parturition even if the perinaum proper is not torn, and if the condition found in those who have not borne children is to be assumed as the proper condition for all women, then an operation may easily be found "necessary" in practically every woman who has had children.

I am free to state that I have not found that patients with slight perineal laceration (and many have come under my notice) have suffered from this condition the direful symptoms which have been described as accompanying such lesions. It has been truly said that the sole justification of any operation must be the strong probability that compensating good will be the result. Under such a rule of action I believe that the cases of slight perineal lacerations requiring or justifying surgical interference will be few. One writer, after calling attention to the fact that marked lacerations suffered years before sometimes remain absolutely without injurious results, pointedly remarks of women having slight lacerations, "It is significant that they suffer more after their attention has been drawn to the injury." This is a hint enthusiastic operators will do well to consider.

Neither in all cases where the *perinaum is more extensively ruptured* is the operation always advisable. A great American gynecologist has put forth the following as aphorisms: "Given a woman with a perfect perinaum, and the relation of the parts within the pelvis will be perfect: destroy that perinaum and at once the parts will fall out of position; restore the perinaum, and as soon as it is perfect all the pelvic organs will be restored to their normal relations." It is difficult to conceive of teachings better calculated to mislead. The idea that a woman with a perfect perinaum cannot suffer from flexion, version, or prolapsus of the womb, and displacements of the other contents of the pelvis is nonsense, as every physician knows, and that when there is a rupture of the perinaum and at the same time displacement of the parts within the pelvis, the simple repairing of the perinaum is always

¹ On So Called Ulcerations of the Os-Uteri. Boston Medical and Surgical Journal, March 16, 1876.

to insure the restoration to their normal relations of all the pelvic contents is equally absurd.

When the injury to the perineum threatens, if left unrepaired, to impair the supporting powers of, and to produce displacements of, the other parts which are, as yet, in practically normal condition and position, and we can feel that the operation of restoring the perineum is going to remove this danger and relieve and cure the patient, most certainly the operation should be done. But in many cases — nay, *most* cases, this lesion is *only one of a series* of sequences of child-bearing. The woman, with more or less absence of perineum, often, at the same time, has subinvolution of the uterus, the organ being much heavier and much larger than normal, perhaps more or less rupture of the neck of the womb, subinvolution of the vagina, and a relaxed condition of all the tissues of the pelvis, allowing the heavy womb to "sag," or to become displaced in one direction or another.

Since these other results of child-bearing are enough to cause serious displacements and serious symptoms in very many cases where there is no perineal rupture, how, in cases where this lesion coexists, can the simple mending of the torn perineum "restore to their normal relations" all the pelvic organs, "or furnish complete relief to the patient? Now, in just such cases I have known physicians to tell patients that all they needed was to have the perineum restored, and the latter to submit to the operation only to be disappointed in the relief afforded by it. In fact, the patient is often worse off in one respect, after having undergone the operation, than before. It is just this class of patients with heavy wombs and relaxed pelvic tissues who derive the greatest benefit from the support afforded by properly adjusted pessaries. Now, with a more or less patulous vulva the patient can usually learn to manage her own supporter when it is once properly fitted, removing and replacing it herself as is necessary; but the perineum restored by operation, and restored as thoroughly as it usually is by the better operators, *as it must be to afford much support to the parts within*, the patient, as a rule, cannot replace her own supporter; indeed, in many cases can remove it only with difficulty, and therefore for the future is dependent upon the doctor; which is good for the doctor, but bad for the patient.

With this class of patients I believe the perineal operation should be reserved for the cases where supporters alone fail to give the desired relief (and such cases will be common in direct ratio with the physician's want of skill in adjusting pessaries), and those cases where, after the wearing of pessaries for a long time, the patient is so desirous of doing without them as to be willing to undergo an operation, and there is fair prospect, the parts having been kept in position so long, that now, if the perineum is restored, artificial supports can be dispensed with. Few patients are so anxious to throw aside a supporter which has given comfort, and whether they are going to be able to dispense with one permanently is always a question.

The mistaken notion so common among physicians that where a lever pessary is to be worn a firm, solid perineum is necessary for it to rest upon, has doubtless often led to the performance of perineal operations which might have been avoided had the surgeon been an expert in the adjusting of pessaries, and known the fact that well-fitted ones do not rest upon or even touch the perineum or perineal body.

Lacerations involving the sphincter muscle and the rectum of course always demand operative measures.

I have not referred to the *primary treatment of perineal lacerations*, that is, their treatment immediately upon the conclusion of the labor during which they have occurred. This subject concerns the obstetrician as much as it does the gynecologist. On the one hand we have physicians who think the introduction of sutures at this time inadvisable, and, on the other hand, those who declare that the neglect to do this is reprehensible. The following is, I think, a fair general statement of the matter:—

In the great majority of cases sutures introduced with skill immediately after the injury has occurred, keeping the torn surfaces in apposition, will give the woman comfort, and increase the chances of a good union, although, of course, it may not take place. In many cases where the sutures are used they are used with such want of skill and in such bungling manner that they fail to insure apposition of the parts, in fact, act merely as setons to increase inflammatory action, and if a good union is obtained, it is not because of the sutures, but in spite of them. In certain cases, owing to the condition of the puerperal woman, it may be bad practice to attempt the primary treatment of the lesion. Such cases are exceptional, however. The "diminution of the chances of septicaemia" by the closing of ("even slight") perineal wounds, which has been much dwelt upon of late, would seem to have been rather exaggerated.

DIVISION OF THE NECK OF THE WOMB.

It is questionable if any other operation of modern surgery has been quite as thoroughly overdone and abused as this has been. Fortunately, the operation is not now as fashionable as it was some years ago, but the evil effect of the teachings of certain leaders in the specialty has not yet fully passed away.

In the last seven years I have performed the operation but twice. These two operations were done in the earlier years when I was fresh from seeing the practice of those with whom it was a frequent and regular procedure, and whether I should now, with my present ideas, repeat the operation in two similar cases is very doubtful. During this period I have had many patients upon whom I should have operated had I followed the practice of some gynecologists of the day, but I do not think my patients would have been benefited thereby.

The operation is usually done to render the uterine canal patulous and straight in cases where it is supposed to be unnaturally narrow or crooked, the object being the relief of dysmenorrhœa, of sterility, etc., etc.

That cases do occur where the operation is indicated and advisable I believe, but that such cases are very rare I am convinced. It is only a short time ago that the operation was very often resorted to. It seemed as if gynecologists divided the cervix uteri simply because they did not know what else to do. Practical experience soon robbed the operation of much of its repute and glory, but patients still come along, every now and then, who have had the operation done upon themselves or who have been advised to submit to it, when from the nature of their cases such an operation could not prove advantageous. I have had patients who had been told they must be treated for stricture of the uterine canal where the largest sound passed without obstruction to the fundus.

"Stricture of the uterine canal is not infrequently diagnosed when in reality no 'stricture' exists. When there is an inflamed condition of the lining of the womb the calibre of the canal is often much diminished by the coincident swelling, and in cases of displacement leading to hypostatic congestion the consequent oedema and swelling of the uterine tissues often leads to the same narrowing of the uterine canal, which is most readily detected with the sound in the neighborhood of the os internum, that being normally the narrow part. But to treat such cases as though this secondary condition were the prime cause of the troubles present does not seem rational.

"Again, when the examiner finds difficulty in passing a sound, he is very apt to jump to the conclusion that a stricture is present, when perhaps such is not the case, and the fault is his own. Where the old-fashioned cylindrical speculum is used (and no one at the present day would base a diagnosis of stenosis of the uterine canal upon difficulty in passing the sound by the touch alone, and without the use of any speculum) it is, in many cases, an impossibility for any one to be at all sure whether a stricture is present or not; for, owing to the fact that the uterine canal is not in a line with the speculum when the latter is introduced into the vagina, but often nearly at right angles with it, a sound cannot always be readily passed through this speculum into a normal uterus. The valvular specula are rather better in this respect, but may lead to error in another way, as I have several times seen. Unless carefully managed the end of that blade which lies along the anterior vaginal wall may very easily be pressed against and be made to indent the anterior wall of the uterus, so as to obstruct the uterine canal to a degree that the sound will not readily pass. The Sims speculum shows its superiority here as elsewhere, but its proper use necessitates the aid of a trained assistant."

It is suggestive that at a meeting of specialists, not a great many years ago, two practitioners, each of great experience, and with large practices, discussed the subject of uterine stricture. The one thought that it practically never occurred at the os externum, but was more common at the os internum, while the other held exactly the opposite opinion. I believe it is rare at either place to the extent to require surgical interference. In some cases where the physicians have considered the uterine canal too narrow or crooked they have recommended the surgical interference when there was nothing whatever to indicate that the condition caused symptoms. Could anything be more ridiculous than such advice given in the case of an unmarried lady whose menstruation was painless. (The lady afterward came to consult me, and asked if I would recommend the operation.) I even know of an instance where a physician, recommending the operation because he thought he found the uterine canal more crooked than usual, and being met by the patient remark, "But, doctor, I never have pain when unwell," replied, "But you may have pain in the future if the womb is left as it is." This was certainly a marked example of preventive medicine or rather preventive surgery! Some time ago I reported, in conjunction with Dr. A. N. Blodgett, of this city, a case of uterine fibroids where the uterine canal was so crooked and narrowed that a small probe could not be passed. Indeed, it was difficult to trace the canal on section of the uterus post mortem. Menstruation had been al-

ways painless! It is interesting to think of these two cases in the same connection.

Division of the cervix to straighten the uterine canal where its crookedness is due to uterine flexion is an operation the beneficial results of which have been very much overrated. There are better and simpler ways of treating uterine displacements, and when these fail division of the cervix will rarely prove beneficial.

The operation itself is very simple. Any one can do it, but no one can truthfully assure his patient that it is unaccompanied with danger. I have seen more than one very serious result follow. To be sure when they come they are generally attributed to the fact that the patient has "taken cold," or to some cause other than the operation itself, but safe to say in most of these cases the trouble would not have come but for the interference of the doctor.

(To be concluded.)

RECENT PROGRESS IN DERMATOLOGY.

BY EDWARD WIGGLESWORTH, M. D.

INFANTILE ECZEMA.

DR. BULKLEY treats¹ of the management of eczema in children under five years of age in his usual practical and sensible way. The disease is by no means hereditary, and is not contagious. The child having the disease may be apparently the healthiest one of the family, yet there is some condition to be corrected besides the disorder of the skin. The mother of a nursing, from a diet of tea or fermented liquors, or otherwise, is dyspeptic, or constipated, or the urine shows derangement of digestion or of assimilation, oxaluria, etc. She should drink milk only, and that with a little alkali added, for example, fifteen drops of liquor potassæ to the tumbler of milk. Mother and child may each need tonics, cream, and cod-liver oil. Gross errors in the diet of the child may often be detected, even among the better classes, for the nurses come from among the more ignorant part of the community, and practice as they themselves have been taught. Constipation in a child under one year of age calls for six centigrammes of calomel rubbed up in sugar in the morning. Three centigrammes should be added for every additional year of life. These every second day or as occasion demands. So also lactopeptine in orange-flower water, after eating. If more is needed give oatmeal or cracked wheat, as a pulp made by rubbing thoroughly-boiled meal through a fine sieve. Young children bear also alkalies well. In old cases, after the first year of life, one drop of Fowler's solution of arsenic in cinnamon water or wine of iron, or six centigrammes each of rhubarb and soda in five grammes of peppermint water. The anæmic child calls for tonics, the full-blooded child for purgatives and alkalies, and only later for tonics, for eczema is a disease of debility. Local eczemas from external irritants call for no internal treatment. Zinc ointment, if used, should not be benzoated. In early stages subnitrate of bismuth, one part to ten or fifteen of rose ointment. Tar only in the latter stages, and then only three parts of tar ointment to one of oxide of zinc powder in eleven of rose ointment makes one of the most valuable anti-pruritics in eczema. All ointments should be applied

¹ Reprint from Trans. Med. Soc. State of New York for 1880.

on cloths, rubbing them in does often more harm than good. Soap and even water does harm in the early stages. If water is employed it should be distilled or boiled, rendered slightly alkaline, and used only for gentle wiping. If oozing exists a drying powder is called for, and washing is only needed at long intervals to remove any very thick crust, impenetrable by ointments, and even here cod-liver oil locally is often preferable. It is not once in one hundred cases that one poultice is called for, and continuous poulticing is very bad practice. Actions for malpractice will soon begin to be brought against general practitioners who refuse to profit by the experience and teachings of specialists. Where an old eczema is dry and scaly, equal parts of oil of cade, green soap, alcohol, and water may be gently rubbed on with a damp cloth, then the parts dried, and the appropriate ointment immediately applied upon a rag. One part of oil of cade or tincture of camphor in nine of ointment is a valuable antipruritic. Stronger ointments usually do more harm than good. In very old cases, obstinate and with localized patches of chronic infiltrated thickening, it is at times allowable to use one part of citrine ointment diluted five or more times. Avoid a routine treatment by arsenic and zinc ointment, and, above all, *never* talk of "driving in," or be led by ignorance and carelessness to assert that it is "dangerous" or "useless" to treat this disorder.

MULTIPLE NEUROMA.

Dr. Carl Rump furnishes¹ the results of macroscopic and microscopic dissections in the case of a man aged thirty-nine, dying of tetanus rheumaticus, clinically, and of fibro-neuromatosis, anatomically. A brother, aged twenty-two, shoemaker, had died previously, and upon the body of this patient Genersich had found,² in various places, numerous nodules following the course of the nerves. Dr. Rump's case was also examined by Rindfleisch and Schottelius.³ The patient had noticed the little tumors five years before death. They never caused pain; confirming the dictum of Gerhardt, "multiple tumors are rather to be regarded as neuromata, the less painful they are spontaneously or upon pressure." The case was one of fibroids of the nerves, the "false neuromata" of Virchow. Many nodules existed upon the same nerve, like beads upon a rosary. When a nerve thus affected branched, its branches were similarly affected. Nodules were found upon all nerves, spinal, cerebral, and sympathetic. The cause may have been a sympathetic paralysis of the vessels of the nerves, for the vessels around and within the nerves were filled with many cells. The mother died of cancer, and heredity may have played a part, both brothers being sufferers. Elephantiasitic processes were also suggested, the cutis being implicated, as was shown by the presence upon the trunk of numerous atheromata and very marked pigmentations.

SYPHILITIC MUSCULAR CONTRACTION.

Dr. Van Harlingen gives⁴ three cases of this rare form of disease, for, though no structure of the body is exempt from the influence of the syphilitic poison, yet the muscular tissues are among those most rarely attacked. When invaded the lesion may occur at any

period of the evolution of the disease. The contraction occurs by preference in the biceps brachialis. Next in frequency the triceps brachialis is attacked. The left side suffers more than the right, and is usually the only side invaded. The diseased muscle is unchanged in form and consistency, but the forearm is flexed upon the arm at a variable angle. Within this angle the limb can be moved, but extension beyond a certain point is impossible, and the attempt at forcible extension is accompanied by pain referred to the insertion of the tendon in the radius. If the triceps also is affected, neither flexion nor extension is possible. The muscle is indolent, no pain on pressure, rarely exaggerated sensibility. Pressure on the tendon develops tenderness. General pain, with stiffness, soreness, and occasional cramps, are usual throughout the muscular system, especially stiff neck coming on towards night. The contraction develops insidiously, and, if untreated, runs on with remissions and exacerbations for a year or more. It occurs from the sixth to the fifteenth month, in light cases, where the skin lesions have been dry rather than ulcerative. The nervous element is often prominent. Neither age, sex, nor occupation seems to exert a causative influence. Pathology, negative; "we see an effect of which we cannot explain the cause." Treatment, "mixed."

ROSEOLA UTERINA.

Dr. Kidd brought⁵ to the notice of the Dublin Obstetrical Society a disease differing from the scarlatinous-erythematous dermatitis, occurring in puerperal women, of Ziemssen's Cyclopaedia of Medicine (Thomas). It not only occurs with patients in childbed, but may follow even trivial operations upon the uterus in women who have never been pregnant, and has been noticed in at least three per cent. of the writer's midwifery cases. From the third to the fifth day after delivery the skin of the abdomen becomes itchy; broad erythematous patches are found, which, in a few hours, spread over this whole region, resembling a mild scarlatina. Next day the axillae are affected, whence it spreads over the chest and neck, but not over the face, then down the arms, thighs, legs, and over the back, always in broad patches. No fever. Pulse and temperature normal, lochia and milk unaffected, appetite good. No headache nor inflammation of tonsils. In two or three days it fades as it came, except that upon the abdomen the patches may remain five or six days. No desquamation, affection of kidneys, nor œdema of extremities, and convalescence is in no way retarded. Neuropathology affords the most feasible explanation of this pathological process, which view, as far as the causation by vaso-motor paresis of affections of the skin, is supported by Hebra, Handfield, Jones, Bulkley, Woaks, and many others.

SULPHIDE OF CALCIUM FOR SUPPURATING RUBOES.

Professor Otis, following the suggestions of Ringer, employs⁶ sulphide of calcium, with the best results, in cases of threatened suppuration in phlegmonous swellings, 0.005 gramme every two hours, or 0.003 gramme every hour, during the day. Furuncles and abscesses are arrested; suppurative processes of the mucous membranes, on the contrary, not. Absorption of pus already formed, and resolution of the tumor, occurred in fifteen out of eighteen consecutive cases of inguinal

⁶ New York Medical Journal, May, 1880.

buboes associated with chaneroid, this resolution tending to prove (in accordance with the popular teaching) that the buboes were of sympathetic and not of chaneroid origin. Applying to these cases of inflammatory buboes, the concomitants or immediate sequela of well-pronounced chaneroids, the old rule that chaneroid buboes always eventuate in chaneroid abscesses, always suppurate, and require evacuation, then we must hold that only three out of eighteen cases of inflammatory buboes, associated with chaneroids, were the result of transference of the suppurative process from the chaneroid to the adjacent lymphatic gland. Or the influence of the drug may extend to the true chaneroid bubo. At all events its successful use invites a trial of its efficacy in *all* instances of threatened glandular suppuration.

PURPURA HEMORRHAGICA.

Dr. Finny reports¹ three cases of purpura, all forms of which (excepting only the purpura of fever) he would classify under the common head of P. hemorrhagica, as exemplifying various degrees of cutaneous hemorrhage rather than different species, the varieties depending, not upon any differences in crasis or in the condition of the blood and its relation to the cutaneous capillaries, but upon non-essential concomitants. Thus, P. simplex has neither the painful affections of the joints characterizing P. rheumatica, nor the hemorrhages from the mucous tracts, giving the distinctive feature to P. hemorrhagica (morbus maculosus Werlhofii). His view as to the pathology of purpura is that the nervous system is primarily at fault, and that through the influence of the vaso-motor system, the blood and the capillaries are secondarily affected. During the attack he advises the use of ergot to induce vaso-motor spasm of the capillaries, and check the tendency to transudation of the blood corpuscles through their walls. When the acute symptoms abate, mineral acids and bark. An antiscorbutic diet is of no value.

TRUE MEASLES; MORBILLI (GERMAN, MASERN). "GERMAN MEASLES," "HYBRID MEASLES," "DUTCH MEASLES," "SCARLET RASH," "FRENCH MEASLES," RUBIOLA (GERMAN, RÖTHELN).

Missouri, like Massachusetts, has experienced an epidemic of measles, and Drs. Cartman and Henderson have availed themselves of the opportunity to emphasize "the fact of the duality of the disease." In "rubeola" the eruption (where not confluent) consists of *single papulae*, each one surrounded by a *separate, small, red areola*. Not infrequently the papulae are large, a few of them passing at times into vesicles or even pustules. The catarrhal symptoms are not very strongly developed, there being less coryza, less ophthalmia, and less photophobia than in true "morbilli." On the other hand, there may be, from the first, severe pharyngeal inflammation, often involving the tonsils and Eustachian tubes; glandular disturbances are more frequent; bronchitis rarely assumes a threatening character. Among the *sequela*, pneumonia of the right lung, abscesses in various localities, and sometimes nephritic troubles occur. In "morbilli," or true measles, the *papulae* are *very small, mostly multiple*, from four to six upon a single areola, which is larger than that of rubeola. This appearance does not seem to be

occasioned by confluence, but is repeated in many spots distinct from each other. A crescentic arrangement occurs at times. The papulae are less prominent; vesicles are rare on the areola, though miliary vesicles without any areola are sometimes found.

The *catarrhal symptoms* are well-pronounced, ophthalmia and coryza often prominent, photophobia at times extreme, severe bronchitis, with little participation of the throat. If pneumonia supervenes, it is usually *left-sided broncho-pneumonia*. Kidneys rarely, if ever, affected. The periods of incubation, deflorescence, and desquamation in the two diseases do not differ much. Secondary fever more frequent in rubeola. Röheln (rubeola) attacks persons from infancy to twenty-seven or more years of age, infancy and childhood being the most susceptible periods. Premonitory symptoms usually mild, in some cases absent. The rash may be the sole cause of alarm. The more severe the attack the more nearly does the rash, as well as the other symptoms, resemble scarlet fever. Desquamation may occur. Röheln does not protect against scarlet fever or measles, nor do either of these protect from röheln, and where a patient is said to have had measles twice there is generally good ground for believing one of the attacks to have been rubeola. This disease is very slightly, at most, contagious, and calls for merely anti-febrile treatment. Roseola is, of course, never to be confounded with either of these exanthemata.

INTRA-UTERINE VARIOLA.

M. Depaul reported² to the Paris Academy of Medicine that a woman, aged thirty-three years, presented herself at the hospital March 12th; she was pregnant, and had had variola a few weeks previously, of which, however, she bore no trace. April 30th she aborted; male child, weighing 820 grammes, and apparently dead one month. It exhibited all the cutaneous signs of a non-confluent variola. Upon the placenta were a large number of fattily degenerated villositities, so that it was uncertain whether the placental disease or the variola destroyed the fetus.

M. Blot. A woman, five months pregnant, had visited a friend ill with variola; a few days later, at about the fifth month, she aborted. The fetus was covered with variolous pustules, while the mother had none.

M. de Villiers had seen a similar case in an infant born at the seventh month.

SULPHUR IN SKIN DISEASES.

During the crass ignorance of former days, sulphur was a popular remedy as being "good for skin diseases," undoubtedly because of the remarkable results which followed its use in scabies, and because "good externally therefore also internally." It is of value, internally given, according to Bulkley,³ for eczema of the anus due to piles, by relieving constipation. "Sulphur and cream of tartar," equal parts, *without* "molasses," is the best form, two teaspoonfuls at night in a little water. Sulphide of calcium for suppurating aene, hordeum, furunculosis, and anthrax, and even suppurating buboes, is of great benefit, given in pills of fifteen milligrammes each, four times a day on an empty stomach. Sulphite and hyposulphite of soda and sulphuric acid have also been given with advantage in furunculosis. For reducing cutaneous congestion, as

¹ British Medical Journal, May 29, 1880.

² St. Louis Courier of Medicine, etc., June, 1880.

³ Gaz. heb., May 7, 1880. Ibid.

⁴ Reprint from Arch. of Dermatology, July, 1880.

in the erythemata, urticaria, etc., Startin's mixture is of great service. This is composed of one part sulphate of iron, eight parts each of sulphate of magnesia and tincture of gentian, two parts of dilute sulphuric acid, and twenty-four of water. A teaspoonfull after eating. The chief value of all "sulphur springs" lies in the bathing, fresh air, exercise, rest, variety, sleep, etc., obtainable, and the supervision of the diet by an ever-present physician. Externally, sulphur is an irritant to the skin, and only of value when a stimulant is called for, as in cases of animal or vegetable parasites, or of acne rosacea. Vapor baths of sulphur are useful for tinea versicolor (parasitic), most erroneously styled by old writers chloasma (pigmentation), for rheumatism, and for some cases of syphilis. Sulphur is entirely inappropriate in acute inflammatory skin affections, and useless in hypertrophies, atrophies, and new formations.

ORAL PAPILLOMATA.

Dr. C. J. March reports¹ the case of a girl aged nine, in whom the mucous membrane of the lips from gums to skin, that lining both cheeks as far back as the second molar tooth, and that covering the anterior half of the dorsum of the tongue, were studded with tumors varying in size from that of a millet seed to that of a large pea, sessile, and in contact on the buccal and labial mucous membrane, while upon the tongue the hypertrophy of the papillae ranged from slight enlargement to pedunculate and even lobulate tumors. Epithelium normal. No tendency to hemorrhage nor to ulceration. Tonsils hypertrophied. The affection was symmetrical; the little tumors numbered about one hundred, and began a year before as a few small growths upon the inner surface of the lower lip. No history of any constitutional malady. Under the influence of the local application of a saturated solution of sulphate of iron several times daily the tumors speedily vanished. Iodide of potassium was given internally.

MEDICINAL ERUPTIONS.

Never minding the why or wherefore, and leaving all theories aside, Van Harlingen furnishes² us with an admirable, and the most extensive as yet made, compendium of all cases recently reported of eruptions resulting from the ingestion of drugs, a monograph most desirable at the present time, when experimental therapeutics is rife, in order to draw attention to, and explain the occurrence of, such eruptions as may follow the administration of new remedies. Arsenic, atropia, belladonna, bromine, chloral, copaiba or eubeds, iodine, mercury, morphia and opium, quinine and cinchona, salicylic acid, santonine, and the wood-tar and petroleum derivatives, have all given proof that doses of them, too large or too long continued, or given to patients specially susceptible, may give rise to localized or general exanthematous or other eruptions upon the surface of the body. The article is valuable, and worthy of study in the original.

SYPHILIS OF THE NERVOUS SYSTEM.

Lang calls attention³ to the general error of attributing lesions of the nerve system due to syphilis solely to localized hyperplasie, gummata, and exostoses, and

regarding them as always signs of advanced disease. Exostoses in particular have almost never been found where such cases have been examined post mortem. The fact is that the nerve system is more frequently invaded by *lues* than any one of the internal organs, though the relative frequency of nerve syphilis has only recently been recognized, and this invasion may occur at almost any period, concurrently with the exanthem, or within a few months, or, in a large number of cases, within a year from the infection. Cases are given by twenty-two different writers in support of these statements, and to these are appended six occurring in Lang's own practice in Innsbruck. Nor is it merely the central nerve system which may be early invaded, for with recently-beginning syphilis meningeal irritation may also be present.

ANTHRAX.

Dr. J. T. Woods considers,⁴ in view of the relatively small size of the anthrax mass when first observed, its increase in extent and thickness, its flat character and intense painfulness, that the death of the connective tissue does not immediately occur; that the morbid process is at first acute; that the extension is by cell proliferation, fibres stretching out into adjacent, still vital parts, preventing yielding, explaining the flatness, increasing the pain. The primary sthenic action is shown by the fact that the slough is thicker than the normal connective tissue. The whole mass necroses and degenerates around its borders; the skin yields reluctantly to ulceration in spots, owing to the pressure from beneath, and multiple openings give exit to fluid. Normally, if the patient survives, the whole mass of dead tissue is thrown off, the skin at last yielding sufficiently, and the cavity is filled up by new cell growth. To imitate nature and relieve pain, Dr. Woods passes the point of a hypodermic syringe through the openings and injects into the sloughing mass, in every direction, pure carbolic acid to saturation. Where there are no openings he pierces the intact skin. In a few moments all pain is gone, the skin becomes hard, white, and dead, and is detached in a few days; the interior mass soon loosens, and is easily removed by cutting its few threads of attachment; the cavity rapidly fills up; the cicatrice is small. The patient can go about his business a few minutes after the operation. Pure acid alone must be used, and to complete saturation. If diluted there is danger from absorption.

HERPES PROGENITALIS.

Dr. Greenough calls attention⁵ to the frequency with which herpes appears upon the genitals, and its importance from a diagnostic point of view, and adds his testimony to that of every sensible observer as to the culpable ignorance of practitioners who apply the solid stick of nitrate of silver to lesions upon these parts, thus merely aggravating the trouble and obscuring the diagnosis. Its use is malpraxis almost invariably. The writer gives a very full bibliographic catalogue, notes the tendency of the disease to relapse, and is inclined to think that every patient suffering from relapsing herpes progenitalis has at some previous time been affected with one or more of the venereal maladies, — urethritis, simple ulceration, or syphilis. He distinguishes the disease from zoster, doubts any

constitutional origin or diathesis, and emphasizes the possibility of the abrasion serving as an avenue for contagion, and the difficulty of distinguishing an inflammatory hardness from specific induration. The treatment is simple, — astringent lotions, drying powders, and, above all, cleanliness.

COLUMNÆ ADIPOSEÆ.¹

To the little pamphlet with the above title, by Dr. J. C. Warren, of Boston, we must allude, though so terse and clean cut are its contents that they cannot be condensed into an abstract. The simple fact is that we have here a real addition to our previous stock of knowledge. We have a discovery by one of the best among our very few original investigators. The science of dermatology has been enriched by a true contribution to its histology. Dr. Warren has discovered the existence of slender columns of adipose tissue perforating the thick cutis vera, hardly microscopical in their dimensions, but overlooked unless sections are made through the skin in the proper direction; a well-defined anatomical structure, with constant characteristics, and the existence of which, now amply verified by observations extending over several years, is of great importance in the pathology of carbuncle, sarcoma, naevus, etc. The columns connect the bases of the hairs with the panniculus adiposus; slender, vertical, columnar-shaped clefts extending from the last-named structure, in a somewhat oblique direction, through the deeper and middle layers of the cutis, and terminating at the base of the follicles which rest upon it. These spaces are occupied by adipose tissue in their entire length, and furnish paths by means of which a virus or diseased cells may advance.

"KERION CELSI," A VARIETY OF TINEA TONSURANS.

Atkinson contributes² an excellent monograph embodying his original investigations upon suppurating ringworm of the scalp, a rare disease. Here we find deep-seated follicular inflammation, with lumpy, livid, boggy, semi-fluctuating elevations of the affected surface, tender on pressure, and dotted with pustules around the hair shafts. Incisions give blood or bloody serum. More advanced forms show gaping hair follicles, with viscid, transparent, or semi-purulent glutinous exudation, like honeycomb. When obstructive inflammation of the follicles exists, the fluid collects in pockets, and may call for the lancet or be ultimately absorbed. The hairs reveal abundant fungus. Finally, there is added to the honeycomb condition an acute perifollicular inflammation and free production of pus. The fungus has been destroyed, the hairs swept away, or lie bathed in pus and often matted in texture. Here, of course, we have no longer the parasite, but merely the inflammatory process to deal with. In the earlier pathological conditions the mucoid secretion, favoring the development of the trichophyton, "is a result of a purely catarrhal inflammation of the hair and sebaceous follicles, caused by the irritation of the fungus; the deep-lying situation of the parts involved giving the affection its peculiar features."

—"Ignorance is not so damnable as humbug, but when it prescribes pills it may happen to do more harm." — *George Elliot*.

Reports of Societies.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

SPONTANEOUS AMPUTATION IN UTERO.

NOVEMBER 13, 1880. DR. LYMAN exhibited the patient, and gave an account of this, the second, case recently brought by him to the notice of the society.

The first case, which was exhibited at the previous meeting, was that of a young woman in whom the left arm is wanting two inches below the elbow. There are two puckered cicatrices over the ends of the bones; otherwise the surface is perfectly smooth. She is of a healthy family. The elbow-joint is perfect, and with the short stump she says she can do anything but knit. During the past month Dr. Call has kindly called his attention to another case, a little boy of five years, whom he now exhibits to the society. In this case the same arm is lost at the same point, and the appearances are singularly like those presented in the previous case, with the exception that from the surface of the stump there is a small rudimentary nipple-like projection such as is figured by Simpson.³

Dr. Lyman said that the weight of evidence now seemed to be in favor of the injury being generally caused by the constriction of ligamentous amniotic bands, where the child comes to full term. If caused by the cord, sufficient constriction to separate the bones could hardly fail to arrest the circulation in the cord itself, and thus cause the death of the fetus. It is quite unusual to find a case in which the amputated member is reported to have been found; but a small fetal arm would almost necessarily be lost among the blood clots, placenta, and membranes, directly after delivery, unless carefully sought for, and even then, if the injury had occurred in early fetal life. Dr. Pepper records a case in the Transactions of the Philadelphia Obstetrical Society of a well-developed child with this deformity, where there were neither fibrous bands or shreds attached to the amnion, and where no trace of hand or arm could be found, though thoroughly searched for.

Dr. Lyman referred to a case of partial intra-uterine amputation of left leg above the ankle and complete loss of three fingers, which he reported in Transactions of Boston Society for Medical Improvement in January, 1862, with a diagram.

TWO CASES OF FIBROID TUMOR OF THE UTERUS.

Paper read by Dr. DOE, and reserved for publication.

DR. HOSMER remarked that in the cases of fibroid tumor of the uterus which had come under his observation two facts were apparent: first, the possibility of retrogressive change; second, of spontaneous expulsion. He recalled a case of twenty years ago, in which two pediculated tumors, of the size of small oranges, were attached to the fundus. Four or five years later these were found to have much diminished in size. Another case was that of the wife of a laborer, a multipara thirty-five or forty years old, who had a fibroid within the posterior wall of the uterus. There was some discomfort, but no serious disability, and no hemorrhage. The menstruation was regular.

³ *Obstetric Memoranda and Contributions, volume ii.*

There were no indications for particular treatment, and she was let alone. Four or five years later she had been advised, by a third person, to submit to an operation for the extirpation of the uterus. Dr. Hosmer then found, instead of a pelvic, an abdominal tumor, rising above the brim of the pelvis, still nothing apparently serious nor calling for active interference; moreover, there was a family of children needing care, and the patient was advised not to undergo the risks of the operation. Four or five years after this question of operation had been considered, Dr. Hosmer again saw her, and found the mass very greatly diminished and wholly within the pelvis. With regard to spontaneous expulsion, Dr. Hosmer referred to a case reported by him at former meetings, and on record in the files of the society.¹

Dr. Hosmer stated that he practically knew nothing of the effect of ergot on uterine fibroids.

DR. SINCLAIR observed that in the matter of interference in these cases we were governed very much by circumstances. If the tumor were giving no trouble it should be let very severely alone; if at the climax of life, it was likely to diminish in size. His only criticism on Dr. Doe's first case was that he should have operated earlier. Atlee's method, he said, was published twenty years ago. As to ergot, he had had little experience with it.

DR. BLAKE stated that he had seen Dr. Doe's second case in the hospital. A point of interest was the differential diagnosis. Dr. Blake referred to a case which had been under the care of Dr. Davidson, of South Boston. In Dr. Doe's case there were apparently the projection of knees and a well-defined placental souffle. There was nothing in the uterus. Dr. Blake felt quite convinced that this was a case of interstitial pregnancy. The points against this diagnosis were the absence of milk in the breasts, and the rarity of the disease. Dr. Blake referred to a book by Dr. Parry, who reports most extraordinary conditions associated with extra-uterine fetation. In the case in question, later, there was less reason to adhere to the diagnosis of pregnancy; the growth had ceased, there was no quickening. General debility interfered with a surgical examination. Dr. Blake had thought at one time of making an abdominal incision for the purposes of diagnosis and possibly treatment. The case was very interesting on the ground of the uncertainty of making a positive diagnosis in the abdominal cavity. A patient seen fifteen years ago presented an interesting fibroid in the anterior wall of the uterus; she had been subject to attacks of retention of urine. These have passed away, the tumor has diminished in size, and the woman is now strong and hearty, and free from all urinary obstruction. As to the treatment, Dr. Blake believed in getting rid of these tumors when they become troublesome, but not before. In Dr. Doe's case he would have removed some portions of the mass at an earlier stage. He had been unable to perceive any benefit from iodide of potassium or from ergot.

DR. RICHARDSON stated that at the Massachusetts General Hospital he had seen several cases in which treatment had failed completely; he had also seen cases in which, under long-continued treatment, the tumors have diminished or disappeared. In two cases recently under observation, the tumors have ceased to

grow, although increasing when the ergot was begun. Dr. Richardson remarked that, as Dr. Hosmer had already stated, these tumors do sometimes disappear during pregnancy as well as at the climacteric.

DR. LYMAN reiterated Dr. Sinclair's statement that incisions into uterine fibroids for arrest of hæmorrhage and as an aid to enucleation by gradual disintegration of the growth were practiced by Atlee thirty years ago. The trouble in Atlee's cases was that he was not active enough in his treatment to forestall septicæmia. The more modern method, to proceed at once to enucleation, is better; incisions alone, leaving the expulsion of the mass to the contractile efforts of the uterus after disintegration and sphacelus, is dangerous in the septic point of view. Dr. Lyman stated that he had in mind fibroids,—one of them was seen fifteen years ago,—very large, painful, and dangerous from the hæmorrhagic exhaustion, which had diminished under the use of ergot unaided by incisions or other interference, and especially is this true after the menopause. He expressed surprise at Dr. Richardson's remark that fibroids disappear during pregnancy. On the contrary, they increased in size *pari passu* with the uterus, and *after* the pregnancy undergo involution even more rapidly than the body of the uterus itself; and he also stated that the growth of uterine fibroids was more readily arrested, and that the ergot acted better if the cervix, that is, the circular fibres of the inner os uteri, were dilated by tents. The same process will also greatly modify and often wholly arrest the hæmorrhage. In reference to a point of diagnosis, Dr. Lyman reported a case, recently under his care, in which he had made a false deduction from the indications afforded by the uterine sound, so much relied on in the differential diagnosis which, when the tumors are interstitial or submucous, will generally pass from three to five or six inches or more into the uterine cavity. The patient, forty-four years of age, entered the hospital October 18th. The case was apparently a typical example of uterine fibroids. The tumor exhibited the hard nodular feeling without fluctuation, and extended as high as the umbilicus. The sound, curved sharply, was introduced two or three times to the depth of four inches. There were severe hæmorrhages and pain in the groins. Per vaginam, the uterus moved freely with the tumor. The vagina and cervix healthy. A large laminaria tent was introduced in the morning and removed in the evening. The next day the patient reported the most comfortable night for a long time. She was free from hæmorrhage and pain, and continued so for about three days. At this time the cervix was much more movable, but the sound could not be entered deeper than before. Two weeks later a second tent was inserted. Four days after this pain recurred without hæmorrhage, and the patient soon died. At the autopsy the uterus was found to be of *normal length*; posteriorly and above it was firmly connected with a large mass of colloid. There was general peritonitis.

Dr. Lyman said that he felt bound to report this case from its value in a diagnostic point of view. The density of the tumor, its uniform development in the central line, its lobulated character, the hæmorrhagic antecedents, the depth of the uterus as measured by the sound, and its mobility when the tumor was moved, all in his opinion justified a diagnosis which the autopsy proved to be an erroneous one. The point which in his opinion was the most interesting one in

¹ For the first report in this case see Boston Medical and Surgical Journal, vol. ciii. p. 546.

connection with the diagnosis was the depth to which the sound penetrated. The measurement, which was made on two separate occasions, he has no doubt was a correct one, notwithstanding that at the *post mortem* the uterus was found to be of normal length. This is only to be accounted for by the stretching of the supravaginal portion of the cervix over the front of the tumor while *in situ* during life, but which when separated from its vaginal and other attachments was restored to its normal length. There were evidences, as will be seen, not only of previous peritonitis, but of a more recent exudation, which may have been excited by the use of the tent, or may have been merely the result of the ordinary extension of the disease. The fact that the patient was more than usually comfortable for some days after the tent was used renders it quite as likely that the manipulation had no influence upon the result.

DR. BLAKE observed that tents sometimes gave rise to violent peritoneal inflammation, or pelvic abscess, resulting occasionally in death. He would not himself use a sponge tent under any consideration, and objected to laminaria as liable, in consequence of uneven expansion, to cause laceration during withdrawal. Unless the benefit and necessity were perfectly plain he would hesitate to employ a tent.

DR. RICHARDSON said that he would agree that although tents may arrest hemorrhage they do not more than incisions avoid the risks of septicemia.

DR. LYMAN said he was perfectly aware of these objections, but that he was satisfied that the danger from tents, if properly used, was very much like the danger formerly attributed to the use of the forceps, the dread of which, like that of some religious prejudices, it seems to take a lifetime to live down. He could recall an instance where the use of two tents was followed by death, but in that case nothing at the autopsy demonstrated cause and effect.

DR. SINCLAIR inquired whether in the case reported by Dr. Lyman the sound had been introduced before or after the dilatation.

DR. LYMAN replied that the measurements had been taken before and afterwards.

DR. SINCLAIR stated that as a rule the uterine cavity would be found diminished in depth a few days after dilatation of the cervix.

DR. FIFIELD remarked that he had been interested in reading an account of the removal of a fibroid by Dr. T. G. Thomas, where very free hemorrhage followed the first incisions, yet the operator had not feared to go on, believing that the loss of blood would not be increased, but rather lessened as the deeper structures should be reached. An account of the removal of a uterine fibroid by Dr. Mary P. Jacobi, by means of Thomas's serrated spoon, had quickly followed the case of Dr. Thomas. Here, also, the amount of bleeding lessened as the operation proceeded from circumference to centre. The explanation of this lessened hemorrhage seems well given by Dr. Putnam Jacobi in the paper, and the truth of the explanation shown by various sections practiced at different parts of the tumor, namely, that some uterine fibroids taking their initial growth from the tissues just beneath the mucous membrane, are increased towards the cavity of the uterus, the older portions being pushed to the uterine wall, becoming more and more dense and bloodless as the growth increases, whilst the outer, younger layers are extremely vascular.

DR. HOSMER mentioned the case of a patient whom he first saw when very near her end, and who was said to have an abdominal tumor. He found by vaginal examination what appeared to be a large fibroid of the anterior wall, but this opinion was not confirmed by abdominal palpation. The patient died of tubercular peritonitis. There was found a small fibroid in the right groin, and the whole floor of the pelvis was thickened, firm and unyielding.

DR. LYMAN said that he had never seen a fibroid in layers, or more vascular in one part than in another.

DR. BOLLES, questioned as to the structure of fibroids, said that his examinations, mostly of the gross appearances in the autopsy-room, showed that the growth was apparently from a centre in all directions, and not from the mucous membrane into the parenchyma of the uterus, that they were often in the midst of the muscular tissue, and not connected with either the mucous or serous surface.

DIFFICULT LABOR; RUPTURED PERINEUM; FEVER; RECOVERY.

DR. FIFIELD reported the case. The patient had been delivered two years ago by Dr. Fifield; the delivery was accomplished by forceps, requiring all the strength that the operator possessed to terminate the labor. The getting up was not satisfactory. A little daily fever, temperature not exceeding 100° F. A little occasional difficulty in urinating, requiring the use of the catheter two or three times during the month succeeding the labor. Then a sudden flashing out of alarming symptoms, high fever, incessant vomiting, only controlled at last by subcutaneous injections of morphia, absolute impossibility of urinating, formation of a huge tumor in the right hypogastrium, which slowly disappeared after repeated blistering.

At the second labor the anterior fontanelle was opposed to the symphysis pubis. Dr. Fifield early applied forceps, and exerted his full measure of strength, but failed to move the head in the least. No unreasonable prolongation of the effort to deliver was made after it was found that no effect followed the application of the full force of the operator. Dr. C. E. Stedman was then called in consultation, and made repeated efforts in vain, the woman lying on the left side. She was then changed to the dorsal posture, the feet in chairs. By most powerful efforts Dr. Stedman finally delivered a male child, whose face and neck were black, and, what seemed very unusual, the very soles of the feet were black. After an hour's labor resuscitation was accomplished. The perineum had been ruptured well into the rectum. It was operated upon after the method of Goodell, Gunrig's perineal needle being used. Silver sutures. At the conclusion of the whole operation the pulse was found to be rapid, 120 per minute. Next day the temperature and pulse were both increased, and on the day succeeding this she showed a temperature of 106° and a pulse (as well as could be counted) of 140 per minute. The patient was now rolled in sheets thoroughly wet with cold water, blankets dry and warm above the sheets, pulse and temperature being considerably reduced thereby. The next day pulse and temperature again advanced to the former point and frequency, and was again reduced by the same means. Friday, temperature being at 105°, a carbolic acid vaginal injection was administered. Patient exceedingly loth to take stimulants or even to take any nourishment. On Sunday, a week from the

delivery, Dr. Chadwick was seen in consultation, the diagnosis considered doubtful, between septicaemia, latent peritonitis, or pelvic cellulitis. Dr. Fitch subsequently gave the patient fifteen grains of calomel on the tongue. Several rattling dejections occurred on the following day, causing some alarm, but the first marked decline of the fever was then perceived. The diarrhoea being controlled by opiates pulse and temperature rose; it being then allowed to proceed to three, four, or even five discharges, pulse and heat fell. Thus, for several days, diarrhoea, fall of temperature and pulse; constipation, rise of pulse and temperature. At length the bowels became regular, and the patient quite rapidly entered into full convalescence. But most surely she never gave hope of emergence from her alarming condition until the coming on of diarrhoea after the administration of calomel.

Schroeder, in his *Manual of Midwifery*, chapter on the Pathology of Child-Bed, Art. Puerperal Fever, says, "In the last century purgatives were used in the treatment of puerperal disease, and recently they have been praised by Dr. Latour Seyfert, Breslau. *A priori*, there is a good deal in their favor. If we may expect to remove the septic material from the blood there can be no doubt that the best way is through the intestinal canal. Observation has also taught us that dogs poisoned by septic matter recover after profuse and fetid diarrhoea."

It is undeniably true that peritonitis, when seen early, can be treated as successfully by calomel, establishing a gentle diarrhoea, as it has ever been by the heroic doses of opium, now so fashionable a remedy in anything which may be suspected to either be peritoneal inflammation, or even be tending thereto.

It is somewhat remarkable that the torn perinaeum and rectum united, in spite of the violent fever and the poisoning diarrhoeas which occasionally took place, as soundly and well as could be hoped for under the most favorable conditions and circumstances.

DR. BLAKE said that the percentage of slight lacerations that did not do well was very small. In the more extensive lacerations, although a spontaneous cure was possible in the great majority of cases, except the worst, yet an operation secured a better union, with less cicatricial tissue, less being left to be accomplished by granulation.

DR. RICHARDSON, in answer to a question as to the propriety of immediate operation in cases of extensive laceration into the rectum, stated that he would operate at once.

Recent Literature.

A Practical Treatise on the Medical and Surgical Uses of Electricity. Including Localized and General Faradization, Localized and Central Galvanization, Electrolysis, and Galvano-Cautery. By GEORGE M. BEARD, A. M., M. D., and A. D. ROCKWELL, A. M., M. D. Third Edition. Revised by A. D. ROCKWELL, M. D. New York: William Wood & Co. 1881. Pp. xxx.-758.

Books grow. Not only do they increase in numbers, but successive editions of text-books are larger in size and thicker. This is seen in many of the medical text-books, and the above treatise is no exception. In this third edition the pages are larger and are increased in number as compared with the first edition. This is

one of the very few systematic works on the medical use of electricity originating in this country. The principal criticism to be made is that the book is too large. Too much space is given to the department of electro-physics. Those who are most likely to use the book probably have some knowledge of electricity in general, and much that is given is not here necessary, and it is possible to still more condense what it would be desirable to insert. The section on electro-physiology is more necessary, but that also could be very much shortened by a more condensed style of writing. In nearly all works on electro-therapeutics the chapter on instruments is too long; an attempt is made to minutely describe a large number of batteries. The truth is that almost any style of battery made by a reputable firm will answer the purpose for which it is designed; and if a physician has a moderate amount of electrical common sense he can easily learn enough in regard to the instrument to keep it in order, and that is all he needs.

The chapter on exophthalmic goitre is newly written; it is interesting reading, but is not quite what it ought to be. Too much space is filled with the report of the authors' cases, and no reference is made to the experience of others. Chvostek has published more than any one else on this subject, and there is no reference to his cases nor the results he has obtained; his name is not even mentioned.

The next chapter, on Sequelæ of Acute Diseases, is not altogether satisfactory. The author says he has "treated twenty-four cases of diphtheritic paralysis, and with the exception of two, which discontinued treatment almost as soon as it was begun, the results in each were too striking to permit of any doubt as to the efficacy of the remedy." What advantage is it to mention how many cases one has treated of any disease, except as a sort of an advertisement? The reader cares more to know that electricity may be of benefit in such cases, and how to apply the remedy; this is not given with sufficient distinctness in this instance, being mentioned only incidentally in the history of one case, where general faradization was used. Was general faradization used in all other cases? As a fact, however, which lessens the value of the statistics, most cases of paralysis after diphtheria do as well without electricity as when it is used; it is necessary only in the unusually severe or prolonged cases.

Referring to a case by Dahlerup, quoted in the *British Medical Journal* for September 27, 1879, in which the patient died apparently from cardiac weakness after diphtheria, the remark is made: "It is not difficult to believe that the prompt and proper use of electricity might possibly have saved life." This kind of criticism is cheap and easy, but is rarely justifiable, and in the present instance is entirely out of place. Reference to the *British Medical Journal* will show that merely an abstract of a case published in a foreign journal is given, occupying sixteen lines, and even of this the most important symptoms are overlooked or carelessly dropped; there was oedema of legs and lungs, and the urine contained a large amount of albumen.

Considering that this work has appeared in a third edition it is not necessary to say that it supplies a want felt by the profession. It is a comprehensive guide, and has many good features. Some of the imperfections have been mentioned, especially those in two chapters added since the second edition. As a whole the work is commendable, but if another edition is is-

sued its value might be increased by condensing, by omitting some of the two hundred or more cases reported, and by reporting the others more briefly.

S. G. W.

A Treatise on the Materia Medica and Therapeutics of the Skin. By HENRY G. PIFFARD, A. M., M. D., etc. New York: William Wood & Co., 27 Great Jones Street. 1881.

A chronic and cosmical *cacoëthes scribendi* has distended the primæval chaos of medical lore with a protoplasmic literature which the genius of this age of indexes is concretizing into practical knowledge. Summaries and even titles furnish us to-day our tools for work; how these tools were made concerns us less. Every one knows that the thesis of modern times represents merely, as the rule, a dilated summary, and this again only a needlessly expanded title, instead of being rather the detailed proof of the truth of these. Given ten books upon any subject the eleventh is already created, and, for that matter, is often the most valuable one of all.

In the handsome octavo of three hundred and fifty pages, before us, belonging to Wood's Library of Standard Medical Authors, Dr. Piffard has condensed the experience of the past as a guide to the future, having, with his wonted energy, endeavored, as far as cutaneous therapeutics are concerned, to keep pace, through personal experimentation and a study of the results of the work of others, with the rapid progress at present being made through the efforts of Parke, Davis & Co., and other manufacturing chemists, in the development of the materia medica as far as our American flora is concerned. Part I., devoted to materia medica, contains, therefore, matter of special interest. Here are considered, under headings alphabetically arranged, the results of the ingestion and of the local application of drugs upon either healthy or diseased skins. The result is a sort of dermatological dispensatory, and heralds the day of special volumes of this nature for each branch of medicine, not the least value of which will be the proving how the present *rudis indigestaque moles*, as a whole, exceeds the sum of all its real parts. Part I. includes exactly one third of the whole volume, and is essentially the more original part of the work.

Part II. is devoted to therapeutics, and considers cutaneous diseases under three heads: the acute and self-limited, the chronic irremediable, and the chronic without definite limit, but yet curable. The remedies, broadly considered, are hygiene, drugs, electricity, and the actual cautery. The importance of general hygiene should invariably be inculcated upon the patient. A knowledge of its laws on the part of the invalid is too often taken by the physician for granted, while the fact is that ignorance or culpable neglect of these laws is the chief cause of all the ills to which flesh is *not* heir. The purity of the drugs employed is as essential an element of success in treatment as a thorough acquaintance with their effects upon the general system or localized tissues. Electricity is capable of four distinct applications in connection with diseases of the skin. These are to produce *catalysis*, *electrolysis*, *coagulation*, or an *intense heat*. Galvanic electricity is the one usually employed, faradic rarely, and static or franklinic hardly at all. For actual cautery the iron is less valuable than the galvanic cautery, and this is in many respects inferior to the "thermocautery" of Paquelin. The dermal cauterizer is often more valuable

than any of these. "Diatheses" are next considered, of which Dr. Piffard is the *unum-sed-leonem* American champion.

The rest of the volume is devoted to a consideration of the individual pathological conditions which may exist in the skin, and the *questio vexata* of classification and nomenclature, in which the writer differs from the majority of his colleagues in this country, is avoided, as far as possible by arranging the various dermatological lesions alphabetically. This part of the book keeps pace with modern research, and is filled with information and suggestion. A full bibliography comes next, followed by an extended formulary for the internal and external administration of remedies, and an alphabetical index completes what we must regard as a practical and valuable addition to the literature of dermatology.

E. W.

A New School Physiology. By RICHARD J. DUNGLISON, A. M., M. D. Philadelphia: Porter and Coates. *The Human Body.* By H. NEWELL MARTIN, D. Sc., M. A., M. B. New York: Henry Holt & Co. 1881.

Taking thought of the functional integrity of one's organs may not add one cubit to a man's stature, but it will often add many cubits to his span of life. We are always pleased, therefore, to welcome good school text-books in physiology. Two such books have recently been submitted to our inspection. One of them was written by Dr. Dunglison, author of the well-known medical dictionary, and is intended for young pupils in the lower schools. It is elementary in character, and reads easily. Most of the subjects treated are familiar physiological experiences of a child's everyday life, and are therefore well adapted to attract his interest and attention. The language is concise and plain. Where technical terms are unavoidable they are accompanied by brief explanations of their meaning and derivation. The illustrations are numerous, and well executed. Indeed, we find nothing to criticize in the book except the statement that 100° F. under the tongue is a normal temperature. We should dislike to have our temperature stand at 100° F. for any length of time.

Dr. Martin's book is altogether different in its scope and character. It forms one of the "American science series for high schools and colleges," but it can hardly be called elementary in design. Although small in bulk it contains a very fair statement of nearly all the leading physiological topics of the day. It is, indeed, a sort of concentrated extract of the science, and will require considerable outside study on the part of a teacher who wishes to prepare it for ready digestion by his pupils. We think considerable space is wasted on a dry category of bones and other anatomical parts. This space might more profitably be occupied by other matters. In an ideal physiology the description of the anatomy of an organ should be so woven into the account of its functional activity that the student will imbibe his anatomy unawares, as it were.

About thirty pages of the book, in the form of an appendix, are devoted to reproduction. Although this is an important topic, and one in regard to which "young people should be properly informed, yet it is hardly appropriate for study by a mixed class of boys and girls. This appendix, however, is entirely distinct from the rest of the book, and has an index of its own, so that it can be removed bodily, and an expurgated edition thereby prepared.

GARLAND

Medical and Surgical Journal

THURSDAY, APRIL 28, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

BEHOLD HOW A LITTLE LEAVEN LEAVENETH THE WHOLE LUMP.

WITHIN the last two weeks seven or eight cases of a rather mild and ill-defined form of typhus fever have been brought to the City Hospital in Boston. These patients were all members of the same family, and the advent of the disease is clearly traceable to the return of the father from a visit to New York. Now, although the exaggerations of the alarmist are undesirable in connection with the present state of the public health in New York, and the mention of such diseases as plague and cholera is only pertinent as a sort of cold comfort to show that there are severer penalties for the violation of hygienic laws than any as yet incurred, or at all likely to be incurred at this time or in this part of the world, we do feel it eminently right that the actual condition of things should not be disguised, and that the dangers to which the city and State of New York see fit to expose, not only their own populations, but those of other cities unfortunate enough, from a sanitary standpoint, to be in close relations thereto, should be plainly set forth and kept in view. With four or five lines of railway and steamboat connecting the city of New York and Boston, over which a vast amount of travel is daily passing, it is impossible to have such a disease as typhus fever, which has been largely banished from its former haunts in Germany, in Ireland, and Scotland, and which we had begun to think ourselves justified in relegating to the limbo of demons of less enlightened days, it is impossible, we say, to have such a disease threatening to assume an epidemic form in New York without other cities being disturbed thereby and feeling themselves justified in remonstrating vigorously at the continuance of any conditions which favor the propagation of such diseases. It is no answer to such remonstrances to say that the disease did not originate in the offending city, but was brought from without. Our quarrel is not with the seed, but with the soil, and with the owner, whoever he may be, who neglects it; and though prepared to give due and proper attention to the care of our own patch, we feel that our neighbor, although a sovereign State, has no right to force upon us undue labor and anxiety.

Crowded tenement houses and insufficient fresh air are even more favorable to the spread of typhus fever than filthy streets. Dr. Russell, of Glasgow, than whom Great Britain has no better health officer, believes that a dwelling containing the proper number of cubic feet of good air to each occupant is almost proof

against typhus fever, and his sanitary administration of Glasgow goes far to show him right.

Again, the season is not far distant when typhoid fever will begin to demand its yearly tale of victims, and we may be sure that from July onward the number in New York and in cities in connection with it — and what cities are not — will be no less than usual, unless the one reptile, as Hirsch thinks is its habit, shall succeed in swallowing the other.

If the public authorities had coöperated, in even a lukewarm manner, with private enterprise and benevolence in New York the death-rate of the city for the first three months of this year would not be 29.36, a death-rate which, accompanied by a constantly increasing weekly mortality, does offer a serious menace to the welfare of that and other cities during the coming summer months.

THE RESIGNATION OF MR. WEBSTER FROM THE MASSACHUSETTS BOARD OF HEALTH, LUNACY, AND CHARITY.

THE resignation of Mr. David L. Webster from the State Board of Health, Lunacy, and Charity deprives the State of the services of a most valuable officer and the board itself of a member it can ill afford to lose at the present time. Mr. Webster, before his becoming a member of the State Board of Health, in 1873, had done Boston important service as a member of the council, especially in the establishment of the city Board of Health, in the management of our public institutions, and in insisting upon a competitive examination for the selection of the city engineer. For a long time known as one of our most intelligent and public-spirited citizens, he entered into the work of public hygiene with such zeal and fidelity, that to his mature judgment and judicial fairness the success of state medicine in Massachusetts has been largely due. His untiring labor, even at the sacrifice of his own comfort and health, his most conscientious fulfillment of every duty, his thorough courtesy and genial manner will long be remembered by his associates in office.

Mr. G. P. Carter has been appointed as Mr. Webster's successor. Mr. Carter is a very respectable gentleman, and was one of Governor Talbot's council; his other qualifications for a position in the health department of the board have not as yet been brought to our notice, and we are inclined to think that he must be a *persona grata* from a political point of view. We, moreover, doubt very much whether in the present condition of the board a thoroughly efficient successor to Mr. Webster or a perfectly independent person could be induced to join it.

Perhaps after politics has had its will of the supervision of the health of this State the public welfare may have an opportunity to be considered. We are evidently, in this State of Massachusetts, on the same road in matters sanitary which has led New York to the slough in which she now sticks, only we have not traveled quite so far. Whether we shall know enough to turn round and retrace our steps before that stage of the journey is reached remains to be seen.

We do not believe that the medical profession of Massachusetts, or at least the more intelligent and disinterested part of it, will ever rest satisfied until the health department of this misshapen board is divorced from the most unnatural union into which it was unwillingly and foolishly forced.

THE HISTORY OF ABDOMINAL SURGERY.

This branch of surgical practice, considered as a legitimate and now indispensable *specialty*, was made the subject of a rapid sketch in one of our recent editorial articles. We therein rehearsed, necessarily in a rather summary manner, a few of the most striking achievements of modern and contemporaneous surgery in this particular branch, not at all with the pretension of minutely or accurately expounding the *history* of its rise and progress, much less with the futile object of attempting to discuss and settle the many claims to the priority of execution of the various abdominal operations which were incidentally touched upon, but simply for the purpose of showing how greatly the field of legitimate surgical intervention in abdominal diseases had been enlarged.

In connection with this subject, and as a consequence of our attempt to deal with it in the manner and with the object just defined, our attention is now called to the entire record of Dr. Gimman Kimball, of Lowell, whom, indeed, we had expressly named among the few surgeons mentioned in our article as having, since McDowell, helped to establish the operation of ovariectomy, and, with it, the present practice of abdominal surgery.

Touching, in the course of our summary review, upon the subject of the removal of the uterus, in cases of myoma, we mentioned only the names of Péan, Koeberlé, and Spencer Wells among the most successful operators. We see no reason, however, why we should not take this opportunity to add the information, now brought to our notice, that this operation has been successfully performed in several cases by Dr. Kimball. In a paper published in Paris in 1865 by Koeberlé on the Suprapubic Extirpation of Uterine Fibroids, the author states (page 59) that the first operation of this kind was performed by Mr. Heath, of Manchester, in 1843, and that the first successful cases were those of two American surgeons, of Burnham in 1853, and of Kimball in 1851. The last-mentioned date, however, is incorrectly given. Dr. Kimball himself, writing in the *Transactions of the American Medical Association*,¹ states that his first successful case of removal of the uterus and of both ovaries was performed in 1853, and was recorded in the *JOURNAL* in May of the same year. Upon seeking to verify the precise dates of these operations, we found that Dr. Kimball's first successful hysterectomy was performed on September 1, 1853, the patient having apparently never been seen by him before the very day on which she underwent this most grave operation; and that the case was reported in

this journal May 3, 1855 (page 249). Burnham's operation, of the same character, also successful, is said by Courty to have been performed on the 25th of June, 1853, and to have been reported in 1854, in the *Worcester Medical Journal*.

In concluding our remarks on this subject, we would say to our contributors and readers that if any one wishes to undertake the difficult task of setting forth, completely and accurately, exhaustively and exhaustingly, the history of the development of abdominal surgery, including the priority of conception, of execution, and of success of each of the operations therein included, we shall be happy to lend our columns for the publication of the valuable historical review, which would doubtless be the result of such investigations, if carried out with the needful patience and labor. Our own editorial duties render it quite impossible for us to undertake at present a task involving such extensive and arduous research.

MEDICAL NOTES.

—The eulogies which reach us from various quarters, of the late Dr. R. O. Cowling, of Louisville, are very glowing, and evidently very sincere. Medical journalism has lost in him an admirable representative, and the profession in Kentucky a member whom the younger men will do well to hold in remembrance for his many fine qualities.

—The Boston Dispensary, which has for over thirty years occupied a building originally intended for two dwelling-houses, is discussing plans for new quarters. The old building is poorly ventilated and two hours' work in some of the rooms exhausts a man's vitality for the whole day.

—Dr. Samuel H. Durgin has been confirmed by the board of aldermen as member of the Board of Health of the city of Boston for three years.

—Ground is soon to be broken on Huntington Avenue for the new Children's Hospital.

—Dr. Hamilton Osgood was a passenger, by the steamer *Atlas*, for Liverpool, on Saturday, the 21st inst.

—The influence of vaccination on the number of deaths is well shown by the statistics of Sweden, where vaccination has long been compulsory. In the prevaccination period (from 1774 to 1801) the average of deaths was 1973 per million inhabitants; in the non-obligatory vaccination period (1802 to 1816), 479 deaths per million; and in the period of compulsory vaccination (1817 to 1877), 189 deaths per million. Thus, the average of deaths in each million inhabitants has diminished from 1973 to 189.

—Baltimore, as well as Boston, is annoyed by a disagreeable and, hitherto, unknown taste in its water. Professor Remsen, of the Johns Hopkins, was detailed by the authorities to investigate the cause, but was not able to arrive at any result. He characterizes the flavor as a "putty taste."

—The *British Medical Journal* has issued an interesting announcement in regard to the

¹ Volume xxv, li. 1877, page 326.

national Medical and Sanitary Exhibition in London:—

"The arrangements for this exhibition are progressing so satisfactorily that it promises to be the most important sanitary exhibition hitherto organized in this country. Applications for space are now being rapidly sent in, as the 31st inst. is the last day fixed by the committee for receiving them. Up to March 15th applications for 984 feet had been received by the committee. The Certificates of Merit which are to be given will be valuable awards to the public and to the successful exhibitors, on account of the high character of the list of jurors, which already includes, among many others, the following: *Medical Section*: Christopher Heath, F. R. C. S., William S. Playfair, M. D., C. Higgins, F. R. C. S., C. S. Tomes, F. R. S., John Marshall, F. R. S., Dr. Robert Farquharson, M. P., the president of the Pharmaceutical Society, C. H. Golding-Bird, F. R. C. S., Lionel Beale, F. R. S., W. B. Carpenter, C. B., F. R. S., J. S. Bristowe, M. D., Major Duncan, R. A., Surgeon-General Longmore, C. B., E. H. Sieveking, M. D., etc. *Sanitary Section*: Sir Joseph Fayrer, K. S. S. I., M. D., F. R. S., George Aitchison, F. R. I. B. A., E. C. Robins, F. S. A., T. Roger Smith, F. R. I. B. A., F. J. Monat, M. D., Alfred Waterhouse, A. R. A., Captain Douglas Galton, C. B., F. R. S., Ernest Hart, M. R. C. S., W. H. Corfield, M. D., William Eassie, C. E., Rogers Field, M. Inst. C. E., R. Thorne Thorne, M. B., Professor Prestwich, F. R. S., etc. In addition to the interest taken in the exhibition by medical men, architects, and manufacturers, the general public have recognized the importance of the work thus initiated by the executive committee of the Parkes Museum of Hygiene, by subscribing to the Guarantee Fund, which, at the meeting of the committee last Tuesday, was reported to amount to £1,026 7s. At this meeting the secretary read a letter from Mr. MacCormac, the honorary secretary-general of the International Medical Congress, forwarding the following resolution, which had been unanimously passed by the executive council of the International Medical Congress at their last meeting: "That the sum of fifty pounds be guaranteed to the committee of the International Medical and Sanitary Exhibition to be held at South Kensington in connection with the Parkes Museum of Hygiene on the occasion of the International Medical Congress."

NEW YORK.

—Notwithstanding the increase of typhus and other infectious diseases, causing a corresponding increase in the already high death-rate of the city, and notwithstanding the most emphatic and earnest public protest of the entire medical profession, as well as the rest of the respectable portion of the community, the lower house of the legislature, greedy of the political patronage of which its members would thus be deprived, still refuses to pass the excellent senate street-cleaning bill, which makes the mayor directly responsible for the proper carrying out of the work required, and the filthy and disease-breeding streets still remain *in statu quo*. The mayor has given the most solemn

assurances that if the matter is entrusted to him he will remove the whole street-cleaning business from the domain of politics, and the best proof that this would actually be the case is found in the fact that he has announced his determination to appoint a man like Lieutenant-Commander Gorringe (who has already secured the necessary leave from the secretary of the navy) superintendent of the department, in case the senate bill should become a law. At the large and enthusiastic meeting of physicians held at Chickering Hall on the 13th of April, special feeling was expressed against the course of Dr. Isaac Hayes (the Arctic explorer), a member of the assembly, who had at first expressed himself strongly in favor of the bill, and promised to exert all his influence in securing its passage, but afterwards not only voted against it, but refused to present a petition of the most influential physicians of New York in support of it, which had been sent him with the confident expectation that he would urge it upon the attention of the house.

—At the meeting of the Board of Health on Tuesday, April 19th, it was announced that there were 103 typhus fever patients in the hospital on Blackwell's Island (being an increase of 47 during the week), and 68 new cases in the city were reported against 55 the previous week. There were 121 patients in the small-pox hospital, and 31 new cases were reported against 51 the week before.

—During the three months ending March 31st, 3616 persons were vaccinated for the first time, and 19,653 were revaccinated by the officers of the board of health, 10,498 of these individuals being in schools and other institutions. This is an increase of 6,663 over the corresponding quarter last year. In his report, Dr. J. B. Taylor, chief of the vaccinating bureau, states that the number of unvaccinated adults in the city is much greater than generally supposed. "Upon reference to the reports of small-pox cases attended by us during the period," he continues, "I find a total of 239 cases, 73 of which occurred among the unvaccinated. In the month of March alone there were 118 cases, 45 unvaccinated. Very few of those who were reported as having been vaccinated have ever had it successfully performed since infancy, and we have never before had so large a number of cases occurring among the unvaccinated in proportion to the total number. There is every reason to believe that there are hundreds, and it may be thousands, of others likewise unprotected among the adults." During the same quarter the sanitary police made 40,295 inspections and attended to 3156 complaints, and the disinfecting corps fumigated and disinfected 321 houses infected with small-pox, 715 with scarlet fever, 613 with diphtheria, 15 with typhus fever, 35 with measles, 35 with typhoid fever, and 17 with cerebro-spinal meningitis.

—About a year ago a monkey escaped from a Bowery Museum and bit off a part of the nose of a little girl. The morsel of the lost member, which was valued by the friends at \$50,000, has been decided in the courts to be worth \$3,500; a verdict for that amount having just been awarded by the jury in the case.

—The Governor has just sent to the Legislature a message relative to the stench nuisances at Hunter's Point and the vicinity opposite New York, which is accompanied by a report from the committee of investigation of the State Board of Health, to the effect that they find that these nuisances seriously affect the comfort and health of the residents of New York and Brooklyn. The message says, "It is a notorious fact that particular kinds of business, including the refining of petroleum, the utilization of animal oil, the manufacture of fertilizers and cream of tartar, and the storage of manure, all conducted on a large scale near the metropolis, have been very offensive from the emanation of noxious vapors. This subject, involving, as it does, the health of nearly 2,000,000 of people, is worthy of your serious attention, to the end that all necessary legislation may be secured to avert the danger now imminent."

—At the last meeting of the Academy of Medicine Dr. Louis Elsberg gave an exhibition of the mode of using the galvanic accumulator (Trouvé's polyscope) for storing dynamical electricity for cauterizing and illuminating purposes, and Dr. M. H. Henry read a paper entitled Remarks on Amputation of Redundant Scrotum for the Relief of Varicocele, Illustrated with new Instruments to Facilitate the Operation. A memorial of the late Dr. Oliver White was also read by Dr. D. Bryson Delavan.

PHILADELPHIA.

—At the last meeting of the Academy of Surgery Dr. J. C. Hutchinson, of Brooklyn, N. Y., read a paper on the Treatment of Hip-Joint Disease, insisting particularly upon the importance of rest and fixation of the joint, and recommending the high shoe on the sound foot, so as to have the weight of the affected limb as an extending force, while the patient was allowed to go about on crutches during the day, while at night extension by weight and pulley is required to prevent painful muscular spasms.¹ The paper was freely discussed, and while general agreement as to the principles of treatment was evident, the greatest diversity in the methods for attaining the desired end was exhibited. Nearly every speaker had a preferred plan for the treatment of hip-joint disease which differed in detail from that of every other. Dr. Hutchinson expressed great satisfaction with the freedom of the debate, in which his method did not escape criticism, but reaffirmed from experience the value of the plan proposed in the paper he had read. His remarks were warmly applauded, and the publication of his essay asked for in the proceedings of the Academy.

—A new gastronomic departure, having for its object the teaching of domestic economy, has been started by the New Century Cooking School of this city. A few weeks ago, a party of invited guests sat down to a dinner which cost eighteen cents per head; last week the same institution excelled itself by inviting a company to what was intended to be a nine-cent dinner, but which in truth only amounted to seven cents per head. Several physicians were among

the guests. The matter is so closely connected with hygiene that we append the following brief account of the entertainment:—

The affair was even more of a success than the eighteen-cent banquet, partly because it was an exploit of still cheaper marketing. "How to market" is as necessary as to know "how to cook," and both are taught in the Girard Street school. The table was spread, as before, with pretty china, and even more profusely decorated with flowers than on the previous occasion. At each plate lay violets with the menu card, and large epergnes alternated with low baskets of choice hot-house flowers, sent in by friends of the school. The bill of fare, as before, was a bill of costs also, and had it not been that the lady managers were put upon the witness stand, and affirmed that it was all true, as there set down, some of the party would have gone away skeptical as to the cost of the substantial meal.

BILL OF FARE.

Dinner, Thursday, March 3, 1881.

Pea soup.

Parker House rolls.

Irish stew. Curly potatoes.

Pork and beans.

Veal croquettes. Cold slaw.

Maccaroni.

Rice pudding. Apple dumplings.

Coffee.

The cost of these dishes was set down as follows: Pea soup: beef, nine cents; peas, five cents; seasoning, one cent. This was a really delicate soup, and it was explained, when the cut of meat was called for, that it was a piece from the shoulder, with very little bone, and that it took a pound and a half, costing six cents a pound. The veal croquettes were made from the neck of the veal, two pounds at five cents a pound, making the cost: veal ten cents; milk, four cents; butter, five cents; eggs, two cents; crumbs, one half cent; seasoning, one half cent; lard, three cents. The pressed soup meat, cost set down above, was also used in making up these excellent croquettes. The Irish stew: mutton, fifteen cents; potatoes, three cents; onions, two cents. Pork and beans, the pork costing twenty-two cents, beans, ten cents. Curly potatoes, which had been put through the colander, and then browned, six cents; maccaroni, ten cents; cheese eight cents. Rice pudding: rice, two cents; milk, sixteen cents; raisins, five cents; sugar, three cents. Apple dumplings: apples, twelve cents; potatoes, six cents; flour, three cents; sauce, nine cents. Coffee and milk: coffee, fifteen cents; milk, eight cents. Bread in soup, the little *croutons*, was sent down at two cents, and the Parker House rolls cost ten cents. All together the bill of fare summed up two dollars and twenty-two cents. As before, the additions to the invited guests put the number actually dining there yesterday at thirty-two, making the actual cost per guest seven cents.

The moral of all this is to show how, given the fire and given the cook, which are both, of course, in every house where a dinner is cooked daily, these *prices, per dish*, are all that it need cost the house-keeper, and she can have the variety for the figures named.

¹ This form of treatment is in use both at the Carney and at the Good Samaritan Hospitals in Boston. —Ed.

Miscellany.

LONDON LETTER: FROM AN OCCASIONAL CORRESPONDENT.

THE following letter from an occasional correspondent in London, gives some additional and curious details of the feelings and comments to which Dr. Quain's attendance upon Lord Beaconsfield gave rise. These details show rather more of the inner history of the question than could be gathered from the somewhat general mention of the subject contained in the letter from our regular correspondent in last week's issue. — ED.

PROFESSIONAL ETIQUETTE.

MR. EDITOR. — The point has been raised, by no means for the first time, in reference to certain facts and individuals, in connection with Lord Beaconsfield's very serious illness, as to the propriety of regular physicians meeting in consultation a reputedly homœopathic practitioner. Your regular correspondent or exchanges may have enabled you to already shock your readers with an account of what some might sensationally style "low life above stairs."

I send you the following, cut from an excellent article in to-day's *Lancet*, from which much may be learned and more inferred: "Dr. Quain has violated a fundamental principle of professional conduct in acting with Dr. Kidd, an eminent homœopath, in treating the Earl of Beaconsfield 'according to the regular practice of allopathy.' This is the conclusion which is forced upon us, and it is one in which we believe the profession will feel compelled to acquiesce."

I will presently give you an extract from last week's *British Medical Journal*, an apparently strangely inspired organ, which has deemed it prudent to remain silent this week on this warm question. From last week's *British Medical Journal*, interpreted by its own silence this week, and to-day's *Lancet*, a very complete view of the points of the case may be gathered.

It is well known that Sir William Jenner had repeatedly resisted overtures made to the end that he should consult with Dr. Kidd, and if it be true that Sir William Jenner and at least one other distinguished physician had declined to meet Lord Beaconsfield's habitual medical attendant in consultation upon the case, before Dr. Quain consented to do so, it is not surprising that that senior practitioner's position appeared to require some explanation. However, 's'excuse, s'accuse,' your readers like all others, who are necessarily unaware that Dr. Quain holds any court appointment, might have a difficulty in properly construing the following paragraph from the *British Medical Journal* of the 2d inst.:—

"Her Majesty, on Tuesday morning, participating in the anxiety felt by his lordship's many friends, desired that further advice should be obtained, and Dr. Quain was requested to attend in consultation with Dr. Kidd. It should be mentioned that Dr. Kidd had for the last three years attended his lordship in like attacks. When this request was made to Dr. Quain he declined, with great regret, to accede to it, under the impression that Dr. Kidd was a homœopathic practitioner. Being, however, assured in the most positive manner that Lord Beaconsfield had on no previous occasion been treated homœopathically, and was not being so treated on this occasion, he sought the advice of

the College of Physicians, who were decidedly of opinion that Dr. Quain would not, under the circumstances, be justified in persisting in his refusal. Those who have known Dr. Quain, and his strict integrity in all that relates to professional honor and feeling, during his long and distinguished career, will at once accord their approval of the course which he pursued under the difficult circumstances in which he was placed."

Additional light having been thrown on the subject, it appears probable that the children of Eve exist on this side of the Atlantic, even in the charmed circle of medical journalism; and also that prudent and experienced Fellows of the College of Physicians number amongst themselves the goose and gander for whom a consultation with a homœopathic practitioner is not common sauce.

On Thursday morning Sir William Jenner consulted over Lord Beaconsfield's illness with Dr. Quain, as a published and distinct favor to the latter, in the absence of Dr. Kidd, who was for the purposes of the consultation to be treated as a non-existent.

Sir William Jenner's unflinching integrity, fearless character, and wide-mindedness have thus been conspicuously displayed, under the most trying circumstances, as an example to all who may be tempted to stray from the jealously-watched course of strict medical etiquette. Let us hope, as I believe, that the medical profession now contains more than one who would decline public honor rather than countenance a practitioner hoisting double colors, would despise ungenerous criticism upon his giving the *congé* to a fashionable, clever, but irregular practitioner of medicine, and would be ready to lend a hand to assist a colleague in a difficult and more or less invidious position, accepted, let us hope and fear, under the inestimable pressure of fashionable and social connections.

LONDON, April 9, 1881.

MASSACHUSETTS MEDICAL SOCIETY, 1781-1881.

MR. EDITOR. — It is proposed to have at the coming centennial meeting of the Massachusetts Medical Society on June 8, 1881, a comparative and historical exhibition of instruments, surgical apparatus, medicines, books, etc., illustrative of the advances which have been made in these various departments. The undersigned, a subcommittee of the committee of arrangements, appeal to the members of the society for the loan of such things as they may possess or be able to command which would be of interest in such an exhibition, and would be glad to be informed *by mail as soon as possible* what articles can be placed at their disposal.

The active coöperation of the members of the Society is earnestly solicited in order that the exhibit may be made as full and interesting as possible.

AN OUTBREAK OF TRICHIINOSIS FROM EATING THE FLESH OF A WILD BOAR.

THE following account, by John Wortabet, M. D., physician to St. John's Hospital, Beyrout, is condensed from the *Lancet*:—

The village of Khiam, where this disease has recently broken out, lies not far from the principal sources of

the Jordan. From the thick jungles of papyrus a large wild boar was shot and brought to Khiam on the 25th of November. This was a great treat to the poor villagers, who can rarely afford butcher's meat, and many of them ate the flesh, raw or half-cooked. The meat was observed at that time to be perfectly fresh and good, but during the second week the persons who had eaten became ill, and if any escaped at that date they suffered later. Of those who had abstained not one fell ill. The symptoms of the disease were the same in all the victims; but those who ate the flesh raw suffered most severely, and the children generally suffered less than adults. The head of the boar was sent as a present to a family some miles north of Khiam, who boiled it very thoroughly before eating it, and though a good number joined in the repast no one of them suffered in the least.

These facts I verified by visiting the place of the disaster, which is a two days' journey from Beyrout, and where I spent January 1st and 2d in studying on the spot the circumstances of the case. I found 257 persons more or less ill,—namely, men 121, women 101, children 35. Five others—three men and two women—had died before my arrival.

As I entered the village I was at once surrounded by some twenty men, women, and children; their faces were still puffy and pale, and they looked very weak, but convalescent. All had one story to tell: "We ate of the flesh, but did not feel unwell till some days after, when we had much pain all over the body, swelling, and fever. We are now much better, but very weak, and not free from pain yet." In examining the cases I found nothing more than they had stated. The tongue was clean, the appetite good, and the functions of the alimentary canal normal. In almost every case, however, there was a peculiar appearance of the floor of the mouth, the inferior surface of the tongue, and the gums. Situated on the mucous membrane there were small white conical projections, a few of which I clipped and subsequently examined with the microscope, but with negative results. The gum often presented congested patches, while at its border it was sometimes red, and bled easily on pressure.

The period of incubation does not seem to have ever been under ten days, though it was prolonged in some cases to twenty. In one individual, who had eaten the meat fairly cooked, the disease did not appear before the end of the fourth week, and then it was so slight that he was not laid up by it. They were unanimous in saying that up to the date of the actual invasion of the disease they felt as well as usual. I heard, however, of one man who had vomiting and diarrhoea soon after eating, probably the effect of an overloaded stomach, and that he was one of those who had suffered the least. The instances in which the disease appeared later than the second week were very few.

The order of the symptoms, after the disease was fully declared, appears to have been, as far as I could find out, a swelling of the face and extremities, accompanied or soon followed by severe pain in all the muscles of the body, and more or less fever, with headache, thirst, perspiration, and much itching of the skin. These symptoms continued about two weeks, and it was during this period that five persons died, apparently from the effects of the fever. The majority of the sick became then slowly convalescent, and left their beds. The number of the sick who were

still confined to their beds could not have been far from one hundred, but most of them were evidently beginning to recover, and with the exception of an œdematous state of the face and extremities, and lingering pains in the muscles, with, perhaps, a slight febrile reaction towards evening, there was nothing particular to observe. The severer cases, which were not more than five or six, presented still the typical features of the disease. The fever was of an asthenic form, in one case with a dry, typhoid-looking tongue, and appeared to be of a secondary character in the chain of morbid phenomena, and probably produced by a general irritation of the whole system. The pain, which invaded all the voluntary muscles, was very severe, but appeared most in the muscles of the extremities at the points of their attachments to the bones. Both flexion and extension were very painful, and the patient lay generally on his back, with his limbs in a state of semiflexion. In one instance I found the calf of the leg hard and very tender on pressure. Every movement gave pain, and the muscles of mastication, swallowing, and breathing seemed to be all equally implicated. The voice was somewhat husky, and there was pain in the region of the larynx. At one time during the march of the disease they complained of a swelling in the tongue, and some had suffered from conjunctivitis, of which I saw two instances. The bowels seemed to have been regular throughout. Some of those who were still sick in bed had been better, but had relapses, attributed to imprudence on leaving their room too soon.

Some ten years ago there was a similar outbreak from the same cause in a village a few miles to the east, when about twenty persons lost their lives. I was told, also, that the wild boar lives chiefly on the roots of the canes which are abundant in the marshes, and as he burrows the ground with his snout he snaps up small animals, such as worms, snakes, and wild rats—the latter of which are said to be sometimes infested with *trichina spiralis*.

Was this outbreak, then, one of trichinosis? No case of death took place while I was there, and to open a grave would have been perhaps impossible. All traces of the boar had disappeared. One brave man offered his arm for examination, but I did not like to inflict pain and injury on the poor fellow, who was still suffering severely from the disease. I heard of a cat which had eaten of the meat and died, but it could not be found. I heard of another in regard to which the statements were very contradictory as to whether it had eaten or not. It appeared well and quite lively. On killing it and examining different pieces of muscle with the microscope, I found them quite healthy and free from the parasite. I still hope to obtain a piece of muscle for examination, and to communicate the result. In the meantime it is quite rational to believe, from the history of the outbreak and from the symptoms of the disease, that we had here an instance of a trichinatos infection on a larger scale than has hitherto been recorded. If it were not that, what else could it have been?

In a postscript the doctor adds: A somewhat aged woman, whom I had seen quite ill when I was there, has since died, and I have succeeded in obtaining a piece of muscle (biceps brachialis), which reveals under the microscope a good number of trichinae, and sets at rest any question as to the nature of the disease. The parasite lies coiled across the primitive fibres, and

apparently within the sarcolemma of the fasciculi, and appears to be free—not enclosed in a cyst. The trichinae may be obtained free of the muscular tissue by a moderate pressure of the covering glass, but they are apt to get thus uncoiled, and to lose their characteristic spiral form. To the naked eye the tissue has a perfectly healthy appearance. A letter from the village states that they were having a good number of relapses, and mentions particularly a return of the swelling, of muscular pain, chiefly at the bend of the elbows and knees, and of much itching over the whole body. The patients complain of a sense of sudden failing if they cannot get food as soon as there is a craving for it. Many are still in bed, and those who are

able to be out feel very weak, and continue to feel pain. I fear there will be more fatal cases.

In a note the editor of the *Lancet* adds: We received from Dr. W. a specimen of the muscle referred to in the postscript, and on microscopical examination found it to contain a large number of non-encysted embryo nematoids. The isolated worms possessed the general shape, with terminal anus, met with in the embryos of trichinae spiralis. They were too immature to admit of any details of organization being made out. They were found to be $\frac{1}{30}$ " long by $\frac{1}{500}$ " broad. The fact that they were non-encysted is in accordance with the other fact that they had not yet attained the usual size of encysted trichinae.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 16, 1881.

Deaths reported 3017; 1058 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 621, consumption 460, lung diseases 453, diphtheria and croup 170, scarlet fever 113, cerebro-spinal meningitis 80, small-pox 58, malarial fevers 44, typhoid fever 40, diarrheal diseases 39, erysipelas 25, measles 24, puerperal fever 15, whooping-cough 12, typhus fever one. From *small-pox*, Philadelphia 37, New York 11, Chicago nine, Brooklyn one. From *malarial fevers*, New York 15, St. Louis eight, New Orleans five, Brooklyn four, Boston three, Chicago and Fall River two, Philadelphia, Baltimore, Cincinnati, District of Columbia and Nashville one. From *typhoid fever*, New York and Philadelphia seven, Brooklyn three, Chicago, Boston, St. Louis, Baltimore, Cincinnati, Milwaukee, and Westborough two, District of Columbia, Pittsburgh, Charleston, Lowell, Worcester, Lynn, Holyoke, Gloucester, and Attleborough one. From *diarrheal diseases*, New York

11, Philadelphia six, New Orleans four, St. Louis three, Brooklyn, Boston, Baltimore, and District of Columbia two, Chicago, Cincinnati, Pittsburgh, Providence, Lowell, Lawrence, and Newton one. From *erysipelas*, New York seven, Chicago three, Philadelphia, Brooklyn, Baltimore, Cincinnati, New Bedford, and Attleborough two, Boston, Gloucester, and Milford one. From *measles*, New York seven, Boston five, Nashville three, Baltimore and Providence two, Brooklyn, Chicago, Cincinnati, New Orleans, and Pittsburgh one. From *puerperal fever*, Chicago three, New York and Brooklyn two, Philadelphia, St. Louis, New Orleans, Milwaukee, Providence, New Haven, Newburyport, and Westborough one. From *whooping-cough*, New York four, Chicago three, Baltimore two, Philadelphia, Boston, and District of Columbia one. From *typhus fever*, Baltimore one.

Twelve cases of small-pox were reported in Brooklyn, 34 in Chicago, one in Boston, seven in Pittsburgh, two in Milwaukee, one in Lowell (also one of varioloid); diphtheria 28, scarlet fe-

ver 11 in Boston; diphtheria 12, scarlet fever 10 in Milwaukee. The mortality from cerebro-spinal meningitis has increased from 65 for the week ending April 9th to 80.

In 45 cities and towns of Massachusetts, with a population of 1,131,247 (population of the State 1,783,086), the total death-rate for the week was 21.43, against 24.16 and 20.71 for the previous two weeks.

For the week ending March 26th, in 149 German cities and towns, with an estimated population of 7,854,993, the death-rate was 27.1. Deaths reported 4098; under five 1885: pulmonary consumption 621, acute diseases of the respiratory organs 441, diarrhoeal diseases 113, diphtheria and croup 129, typhoid fever 77, scarlet fever 70, whooping-cough 45, measles and röteln 42, puerperal fever 27, small-pox (Königsberg two, Lübeck, Tilsit, Munich two, Berlin two, Aachen three, Essen) 12, typhus fever (Königsberg two, Thorn five, Tilsit) eight. The death-rates ranged from 16.5 in Mannheim to 39.9 in Chemnitz; Königsberg 39.5; Breslau 36; Munich 39.6; Dresden 30.9;

Berlin 24.6; Leipzig 21.6; Hamburg 21.8; Hanover 18.3; Bremen 18.5; Cologne 25.2; Frankfurt 20.5; Strasburg 31.8.

For the week ending April 2d, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 21.9. Deaths reported 3196: acute diseases of the respiratory organs 358, whooping-cough 67, small-pox (London 56) 57, measles 50, diarrhoea 36, fever 27, diphtheria 20. The death-rates ranged from 13.6 in Leicester to 28.9 in Manchester; Sheffield 17.2; Birmingham 20.1; Leeds 20.2; London 21.8; Liverpool 24.7; Bristol 26.2. In Edinburgh 18.8; Glasgow 22.4; Dublin 30.8.

In the 20 chief towns in Switzerland, for the week ending April 2d, population 548,301, there were 37 deaths from acute diseases of the respiratory organs, diphtheria and croup 15, diarrhoeal diseases 14, typhoid fever 13, measles eight, small-pox three, scarlet fever two. The death-rate of Geneva was 17.5, Zurich 35.9, Basle 31, Berne 35.1.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 16, 1881, TO APRIL 22, 1881.

MCCLELLAN, ELY, major and surgeon. When relieved by Assistant Surgeon Ebert, to repair to these headquarters for assignment to duty. S. O. 44, Department of the Columbia, April 5, 1881.

BARTHOLOMEW, JOHN H., captain and assistant surgeon. When relieved by Assistant Surgeon Spencer, to proceed to Fort Lapwai, Idaho, and report for assignment as medical officer of that post, relieving Assistant Surgeon Ebert. S. O. 44, C. S., Department of the Columbia.

HELMANN, CHARLES L., captain and assistant surgeon. Relieved from duty at Vancouver Barracks, and assigned to duty as post surgeon at Fort Townsend, W. T. S. O. 44, C. S., Department of the Columbia.

ATSWORTH, E. C., captain and assistant surgeon. Having reported at these headquarters, will report to the commanding officer, post of San Antonio, Texas, for temporary duty. S. O. 56, Department of Texas, April 14, 1881.

SPENCER, WILLIAM G., captain and assistant surgeon. When relieved by Assistant Surgeon Helmann, to proceed to Fort Coeur d'Alene, Idaho, and report for assignment as medical officer of that post. S. O. 44, C. S., Department of the Columbia.

EBERT, R. G., first lieutenant and assistant surgeon. Instructions by telegraph of this date to proceed to Fort Lapwai, Idaho, and relieve Surgeon McClellan as medical officer of that post, temporarily, confirmed. When relieved by Assistant Surgeon Bartholomew, to rejoin proper station, at Fort Walla Walla, W. T. S. O. 44, C. S., Department of the Columbia.

ARTHUR, WILLIAM H., first lieutenant and assistant surgeon. To report in person to the commanding officer, Fort Sanders, W. T., for duty. S. O. 31, Department of the Platte, April 16, 1881.

BUSHNETT, G. E., first lieutenant and assistant surgeon. Assigned to duty at Fort Yates, D. T. S. O. 61, Department of Dakota, April 11, 1881.

BIRMINGHAM, H. P., first lieutenant and assistant surgeon. So much of paragraph 1, S. O. 62, March 17, 1881, from A. G. O., as relates to him, is suspended until May 1, 1881. S. O. 85, A. G. O., April 14, 1881.

WYETH, M. C., first lieutenant and assistant surgeon. Assigned to duty at Fort Meade, Dakota. S. O. 61, Department of Dakota, April 11, 1881.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the society will be held Monday evening, May 2d, at eight o'clock, in the hall of the Medical Library, 19 Boylston Place. Reader, Dr. D. H. Hayden. Subject, Movable Kidney. Election of members.

M. H. RICHARDSON, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED. — Hydrophobia. By Horatio R. Bigelow, M. D. Philadelphia: D. G. Brinton. 1881.

Quarterly Report of Medical Officers, United States Army, with Stations and Duties, April 1, 1881.

Fiftieth Annual Catalogue of the Massachusetts College of Pharmacy. 1881.

A New Cortical Centre. By Graeme M. Hammond, M. D. (Reprint.)

Lectures on Diseases of the Nervous System, especially in Women. By S. Weir Mitchell, M. D. With five Plates. Philadelphia: Henry C. Lea's Son & Co. 1881.

The Education of the Rich. (Pamphlet.)

An Introduction to Pathology and Morbid Anatomy. By T. Henry Green, M. D. Fourth American from the fifth revised and enlarged English edition. Philadelphia: Henry C. Lea's Son & Co. 1881.

Experimental Researches on some Points relating to the Normal Temperature of the Head. By J. S. Lombard, M. D. London: A. K. Lewis. 1880.

Annual Report of the Health Officer to the City Council of Oakland, California, for 1880. E. H. Wooley, M. D., Health Officer.

UNNECESSARY SURGICAL OPERATIONS IN THE TREATMENT OF THE DISEASES OF WOMEN.¹

BY CLIFTON E. WING, M. D., BOSTON.

THE OPERATION FOR RESTORING THE CERVIX UTERI WHERE THIS HAS BEEN RUPTURED. EMMET'S OPERATION.

Curiously enough, while a short time ago "*division of the neck of the womb*" was the gynecological fashion, now its exact opposite, "*the closure of the neck of the womb*," when this has been divided by nature or art, is the popular operation of the day.

When Dr. Emmet clearly described the condition which had been (and, even now, still is) so often mistaken for "ulceration of the womb" and devised an operation which might be employed for its cure, in cases where such a course was called for, he did a good thing for gynecology. In former days "ulceration" was the "*bête noire*" of those who treated women's diseases, and cauterization with nitrate of silver or more active agents was the "proper treatment." Dr. Emmet's exposition of the real condition of the parts has done away with much of this malpractice which had its origin in ignorance. But if every woman with a laceration at the neck of the womb is to be considered a fit subject for a surgical operation, without regard to whether this condition is really a cause of troublesome symptoms or not, then the discovery of Dr. Emmet is to prove anything but a boon to womankind.

Most women who have borne children present more or less of this lesion. Many have rupture and eversion of the neck of the womb without symptoms. Certain ones suffer from this condition. Measures of treatment directed to this lesion, it is needless to say, should be reserved for these last cases, but there is at present, in America, at least, a marked tendency to resort to the operation devised by Dr. Emmet, whenever the condition of eversion is found, whether it be a cause of suffering or not. It is true that by this means the typical conical form of the neck of the womb can be restored, but it is also a fact that very many of these women are not going to be benefited thereby.

A western physician has recently written so clearly upon this operation that I cannot do better than quote freely from his article.² After stating that the operation "has reflected unstinted credit upon its author, Dr. Emmet," he proceeds: "But I am afraid the disposition is just now to a too frequent resort to this serious operation. It is my conviction, and I know that there are many others who think as I do, that this procedure, so useful in its place, is being done far more often than there is any need for, and that there are many who are beginning to look upon it as a panacea for nearly all the forms of cervical disease. All new discoveries have to pass through what might be called an exaggeration period before they at length settle down to their proper level. So with the operation in question. There is something so simple and direct about it as to make it almost captivating to the surgeon's eye. Here is nature at fault, as usual, and art coming triumphantly to her relief with a neat plastic operation. Could anything be plainer? One writer in his enthusiasm advises the

measure even after the ordinary slight laceration of labor; which is simply throwing overboard all faith in the restorative powers of nature. Proceeding on such a rule, nine tenths of parous women would have to be made the subjects of surgical operations. Let it be remembered that a certain amount of laceration accompanies every labor, whether normal or abnormal. Let it be remembered, too, that the cervix of all women who have borne children present evidences of puerperal tearing, all the way from slight irregularities of the os to clefts extending deep into its structure. Is there any one of us who has not again and again found such a condition coexisting with perfect uterine health? . . . As far as my own practice goes, I must admit that at first I was much taken with the operation and performed it more often in former years than of late. There are many others who reckon their trachelorrhaphies in a similar declining ratio, although never ceasing to regard it as one of the most valuable contributions ever made to gynecology. . . . We live and think in cycles. Even fashion is subject to this law, and fashions in medicine have always characterized our science. The fashion of sewing up the uterus as an ordinary therapeutic measure may be expected to have its day, and then its true worth will be recognized — that of a most reliable, but serious and not often demanded, operation."

When gynecologists recognize the truth of this last sentence then . . . real benefits of Emmet's discovery be realized. Its effect so far has been in great measure the supplanting of the old treatment (by caustics, etc.) for "ulcerations" (which never existed), which, although it was misdirected and, in the light of our present knowledge, absurd, — yet was seldom followed by serious or fatal results, — by the performance of surgical operations, alarming to the patients and their friends, and which in a large proportion of cases are uncalled for and can be avoided. The fact is that very many cases of "rupture and eversion" (cases formerly considered "ulceration") require no treatment whatever, *i. e.*, the lesion is innocuous. Physicians have been rather led away by an exaggerated idea of its bad effects. For example, women with this condition have been solemnly assured by their doctors that unless they underwent operation for its cure they would never again become mothers, when perhaps the lapse of a few months has disproved such assertions and left the medical gentlemen in an awkward position.

The cases which are accompanied by troublesome symptoms and demand attention are the exception rather than the rule. If surgical interference is confined to such, Emmet's operation will be productive of much good. As at present often done, not because it is really needed but because a chance for its performance offers, it probably in the aggregate does more harm than good.

The operation is by no means devoid of danger. Phlebitis, cellulitis, pelvic abscesses, septicæmia, peritonitis, etc., have followed its performance by the best operators, and left results from which the patients would recover only after months of suffering, if at all. It is only a short time ago that a discussion in one of our local societies brought out accounts of several deaths after this operation. I myself have known of more than one such result.

The two operations last considered have been referred to, in a letter from London, in the following amusing lines: —

"When Dr. Sims was first here, he demonstrated, to

¹ Concluded from page 392.² Paper read before the California State Medical Society, by W. H. Mays, M. D.

the satisfaction of a great many people, and indeed seemed almost to have established it as a canon in practice, that a great number of women are suffering from complaints which require that the cervix uteri shall be lacerated to the extent of complete division; and we were under the impression that according to the well established experience of Marion Sims and his school, about twenty to twenty-five per cent. of the gynecological patients are required to have the cervix uteri divided in order to be restored to health. But it now we find that at least as many are suffering from complaints which require that cracks, cuts, and fissures of the cervix shall be shut up, it seems as if the greater part of the energies of that most fearfully numerous, highly intelligent, and active class of practitioners, who, either as specialists or as family doctors, have a claim to the title of gynecologists, will in future be divided between splitting up the cervixes of those women who yet possess them entire, or uniting with horsehair or silver wire those which are by nature cracked or fissured. The general moral would then be open to deduction, that in respect to the uterus, whatever is wrong, and whatever is not, ought to be brought about."

This is rather an exaggerated view of the matter, yet there is a good deal of truth in these lines. To my own knowledge, at one time a distinguished practitioner was doing many operations for dividing the neck of the womb, while an equally distinguished brother physician of the same city was industriously closing these cuts by operation and sutures, when the former's patients happened to fall into his hands.

CURETTING OF THE UTERINE CAVITY.

This is an operation which is being frequently performed at present. It consists in the scraping, with instruments devised for the purpose, of the inside of the womb (much as gardeners at certain seasons scrape trees), the object being the removal of morbid growths and excrescences, and the consequent checking of uterine hemorrhage, etc. Formerly by the term "curetting" was meant a pretty serious operation, one which was comparatively rarely done, it being, as a rule, resorted to only when simpler means of controlling uterine flowing had failed, and when, in the absence of other apparent cause of hemorrhage, there was a strong probability that "intra uterine fungosities of intractable nature" were present. To insure the removal of such growths the "curette" or instrument employed had a comparatively sharp (although not necessarily a "cutting") edge. With the increasing interest in the subject of diseases of women, such as has developed of late years, and the accompanying enthusiasm for "operations," naturally there has come an increased number of cases of curetting, until nowadays, if a patient presents herself with a simple uterine catarrh, and a history of increased uterine flow (which is but natural in such cases), and particularly if she have borne children, and has in consequence an "invitingly-open" uterine canal, perhaps the first thing the physician thinks about is the curette. But under this kind of practice the results with the old instruments were unsatisfactory. Too many patients were seriously injured, and some were killed, by the procedure, for even in the best hands, "curetting" if thoroughly done is a dangerous process for the patient to go through, and an operation which should always be kept as a last resort. The result was the introduction of a most formidable instrument in the shape of the "dull curette."

Now in most cases of common uterine catarrh the lining of the womb is more or less inflamed and swollen, and, from the presence of increased secretion, soaked and softened. The use of even a dull curette, under such circumstances, will, almost always, result in the removal of more or less of the softened lining, with, perhaps, a few distended and swollen glands; but in such cases the proceeding is not at all necessary, for, the catarrh checked by proper means, the parts will soon return to a normal condition. I have several times seen the dull curette used under such circumstances, and what were termed "characteristic granulations" removed and exhibited with satisfaction by the operator to those present, when I have afterwards taken some of these "granulations" and "teased them out" under water and seen them resolve themselves into strips of apparently normal uterine membrane, which had evidently been rolled up into little balls before the edge of the curette, as snow is rolled into balls by children, thus deceiving the operator.

The great difference in the views held by physicians as to the dangers of "curetting" is explained by the fact that one set of physicians mean by this term the thorough operation done with the sharper instrument; an operation reserved for cases where other means of treatment have proved of no avail, therefore a comparatively rare operation, and, from the nature of the case, a pretty serious one; while with others of the profession "curetting" is a common method of treatment resorted to whenever any excuse offers, the *dull instrument* being employed. The procedure, as performed under such circumstances, is often hardly worthy of the name "operation," although the opportunity of using this term is seldom missed by those who practice it, and in many cases has very little effect for either good or evil. But this is not true in all cases. In some conditions of the endometrium, where it is in an unhealthy relaxed condition, and it is desirable to "set up a healthy action" as our forefathers in medicine would say, the stimulating effect of the use of the dull curette may prove advantageous, and the dull curette will, in some cases, if used with skill, remove *soft growths* successfully, but it will prove inefficient in the case of many of the harder growths and granulations so difficult to manage with ordinary means, for which the operation of curetting was formerly reserved. Many a gynecologist has learned this fact from experience, and, after several "operations" with the dull instrument, has finally overcome the difficulty by using the sharper instrument. As one writer has said of the dull curette, "It is an excellent instrument where nothing is to be removed;" but in such cases other measures less alarming to the patient will usually suffice.

Although in careful hands rarely productive of bad consequences (even when *used*, and not merely played with, as is often the case), yet there is a tendency in certain quarters to regard the dull curette as an instrument safe for any one to experiment with, and one which the merest tyro in practice need not fear to make use of. A caution may not be amiss. No one

¹ I have been surprised at the way the term "operation" is used, even by some physicians of good standing. I have repeatedly been told by persons who have come to see me about patients coming under treatment that the cases were probably serious ones, because the patients had already gone through so many operations, when later I have found the "operations" referred to, consisted, perhaps, in the application of some mild remedy to the cervix, perhaps, in the use of a uterine sound, or, it may be, in the attempt to place a speculum! Doubtless, such a use of the word has the advantage of making a due impression (?) upon the patient and her friends.

should attempt the use of a curette, sharp or dull, who is not sufficiently experienced in uterine examinations to assure himself of the absence of all pelvic inflammation, even slight. The presence of such inflammation, which, when slight and localized, is not always readily detected by the inexperienced, often leads to uterine flowing; but under such circumstances curetting would probably make bad work. Even the use of a sound is not advisable in such cases. Again, the physician's office, from which the patient must return home, is not the proper place for the procedure. Physicians often ignore this fact with impunity; but I cannot but think it is making the patient run an unnecessary risk. She should be where she can lie quiet for a day or two, and longer if advisable. Occasionally there is severe hæmorrhage with the operation, even with the dull curette, and no one can tell beforehand with which patient it will come.

Dr. Emmet has devised forceps for removing granulations, etc., from the uterine cavity, which are very efficient, and render the resort to curetting but seldom necessary; but I do not think they quite take the place of the sharp curette in all cases. I have used both to advantage in the same case. Once, I recollect, the hæmorrhage was so rapid after removing some growths with the forceps, that I was forced to give them up, and finished the operation successfully by very rapid curetting, which brought away the rest. In certain quarters the "sharp curette" has been decried as a barbarous instrument, one which should never have been invented, etc. It is its unnecessary and heedless use which has brought it into such ill-repute. It need never be so keen-edged as to merit the name of a "cutting instrument," and used with proper skill in proper cases it supplies a place the dull curette cannot fill. Emmet's forceps are excellent for the removal of placental tissue and other products of miscarriage; and here another word in regard to the use of the curette. It should be avoided if possible after miscarriage or labor, while the walls of the uterus are undergoing involution and the accompanying fatty degeneration. (Here Emmet's or other forceps can be used with much greater safety.) I have known neglect of such caution, and the rash curetting of a patient a few weeks after the confinement, followed by fatal consequences.

THE OPERATION UPON THE ANTERIOR VAGINAL WALL FOR PROLAPSE OF THIS PORTION AND CYSTOCELE.

When there is a tendency of the anterior vaginal wall, with the adjacent bladder (cystocele), or without it, to sag and protrude through the vulva, an operation, consisting in either the "folding in" or the removal of the slack of the vagina at this point, has been devised to correct the condition and afford relief to the patient from the "bearing down" bladder distress and other symptoms referable to it.

This "sagging" of the anterior vaginal wall rarely takes place to a troublesome degree unless there are other abnormal conditions present, notably, rupture of the perinæum, or some one of the uterine displacements, bringing the cervix, and with it the upper part of the vagina, nearer the vulva. Oftentimes a "sagging uterus" is present. With an absence of more or less of the perinæum the vagina fails to get its usual support, and with a lowering of the womb the anterior vaginal wall, no longer extended to its normal

length, naturally tends to sag. In this way a low position of the uterus often has much to do with the production of this condition. Unfortunately, in a large proportion of these cases, the conditions named are not the only abnormal ones present. Such patients are apt to have the womb left large after confinement; a heavy weight upon its weakened supports. If such a patient goes through the operation on the anterior wall to reduce the vagina (preceded very likely by the operation for rupture of the cervix, if the physician is enthusiastic over modern operative gynecology) and later the operation for ruptured perinæum, *since the weight of the heavy womb still remains she does not always get as much relief as can be given in many of these cases by the proper adjustment of a pessary without operative measures*, and perhaps after going through all the operations the patient will still have to wear a supporter to be comfortable. Indeed, where there is this heavy womb, with a relaxed condition of the pelvic tissues, a combination often found in practice, it is a very difficult matter and sometimes an impossibility to so constrict the vagina by any operation as to afford complete and lasting relief to the woman. In such cases it is often perfectly feasible, without any operation, to adjust a lever or other pessary, which the patient can herself remove and replace, which will raise the womb into place, and extend the vagina its normal length, so that practically no falling of the anterior vaginal wall is left. If the extending of the vagina is not alone sufficient then the lower end of a lever pessary may generally be so bent as to be of some additional service in keeping the falling anterior vaginal wall in place.

It has repeatedly happened to me to see such patients who, having tried various supporters without relief, had been led to think operative measures necessary, who, much to their surprise and delight, have been relieved completely by the aid of a proper pessary. Some, who had been so thoroughly imbued with the idea that an operation was necessary, if they ever wanted to be comfortable, as to seem almost disappointed when I did not urge such measures at once, have experienced such relief from a pessary as to express indignation that they were ever told an operation was necessary for them.

While I believe of this operation, as I believe of each of the other operations considered, that in its proper place it is capable of much good, yet I believe of it, as I believe of the others, that at present it is done much oftener than is necessary or best.

Patients suffering from these troubles are not infrequently told that they must undergo surgical operations before they will be able to wear a supporter. Occasionally such conditions exist that this is the fact, but with proper knowledge of the adjusting of supporters these cases will prove rare, much less frequent than they are at present considered. Comparatively few practitioners are in any sense experts in the fitting of pessaries, yet a thorough knowledge of their uses is as necessary to the gynecologist as is the knowledge of splints and other apparatus to the orthopaedic surgeon. This knowledge on his part frequently saves his patients from operative interference, and the same is true of a thorough knowledge of the pessary and its uses on the part of the uterine specialist. At present any new invention in the shape of a supporter needs but one thing to make it attain popularity in the profession at once, however it may fail otherwise. If it be only easy of

introduction without paining the patient it is sure of a run for a while at least. The so-called "soft cotton pessary," highly recommended because it can "be worn where the womb is too tender to bear the pressure of a common supporter" (the fact being overlooked that a properly fitted lever pessary does not come in contact with that organ), highly efficient in creating a stench if worn even a short time, and good for little else, but easily introduced by anybody into the patient's vagina without causing pain, is a good example of this fact.

Dr. Engelmann, of St. Louis, has recently published an article entitled *The Dangers Incident to the Simplest Uterine Manipulations and Operations*, in which he has collected many bad results following the common gynecological procedures and operations. Naturally, in recording the bad results, he was confined in great measure to the reported cases. Could he have known of the cases not reported his examples would have been multiplied manifold. I regard the paper as a most valuable one at the present time, and as possible evidence of a coming reaction from the "operation fever" which has afflicted gynecology of late years. It certainly is a warning to the profession not to regard gynecological operations too lightly. If we can go a step further, and lead physicians to realize that the operations now so much in vogue can often be avoided, it will be another step in the right direction.

A former Harvard professor often quoted the saying, "Meddlesome midwifery is bad." He might have truthfully added, "Meddlesome gynecology is even worse."

THE USE OF ELECTROLYSIS IN THE TREATMENT OF HIRSUTIES.¹

BY JAMES C. WHITE, M. D.

THE natural growth of the hair upon different parts of the body varies in amount according to age, sex, and race. Overgrowth in point of extent may be extremely circumscribed, as upon a hairy naevus or wart, or universal; as regards age, it may be congenital or develop any time after birth. The hypertrophy may consist in an excessive development of the usual large and long hairs of the scalp, beard, axillæ, and genitals; of the short hairs which cover the general surface, or of the downy (lanugo) hairs upon the face and other parts of the female, into the strong, visible growth characteristic of the male. It is this latter variety only which demands the frequent aid of the surgeon. For universal hairiness, it may be stated in the beginning, nothing can be done; for the circumscribed forms in either sex connected with pigmented naevi and warty growths, the best treatment, when of moderate size, is the excision of the whole growth. When too extensive for such an operation the hirsuties may alone be treated by the method now to be considered. There is no more distressing affliction to a woman than an excessive growth of hair upon the face, none for which she will more persistently seek relief. It may be confined wholly to the upper lip or to a few sparse tufts or scattered hairs upon or beneath the chin, or to the sides of the cheeks. The mustache may often be long and heavy, and the side whiskers largely developed, while a full, strong beard is very rare, and generally associated with universal hirsuties. Such growths

are by no means infrequent upon the faces of girls after the age of twenty, and the great majority of cases which present themselves to the surgeon and dermatologist for treatment are between the ages of twenty and thirty. These young women are generally in good health, and the hypertrichosis seems to be in no way connected with any apparent disturbance of the sexual apparatus. Later in life, about the climacteric period, the lanugo hairs are apt to increase in size and depth of pigment over similar parts of the face, but such forms more rarely seek professional advice. With the growth upon the face there is often a similar development over the sternum and about the nipples at all ages. In addition to the deformity it gives rise to, the presence of a noticeable beard or mustache is apt to develop a morbidly sensitive condition, which prompts the bearer to shun society, and at times develops into a true monomania. The writer has known a lady who had visited surgeons in all the principal cities of the country in the vain search for one who would flay the whole lower half of the face for the extirpation of the hair growth.

Treatment.—It is only within a short time that a radical method of cure for hirsuties has been known. Previously the three well-known means for the removal of hair could alone be advised by the surgeon, and these had already been resorted to in the majority of cases by the patient. They are not only temporary in their action, but often are of positive injury in the case. These are, first, the method resorted to by the male sex for the temporary removal of the beard, namely, the razor; second, the application of depilatories, which destroy the hair a little way within, in the mouth of the follicles, and which therefore retard the reappearance of the growth a little longer than the razor, which cuts it off at the level of the surface. These depilatories have, moreover, decided disadvantages. They always, in virtue of their caustic properties, produce more or less irritation or inflammation of the skin to which they are applied, which must tend to the stronger development of the overgrown hairs by feeding their vitality, hirsuties, as is well known, not infrequently following the rubefacient action of a mustard poultice to any part of the body. They most commonly consist of mixtures of quick lime and arsenic, of sulphide of calcium, barium, etc. An objection common to them and the razor is that by their use there is substituted for the more delicate and tapering pointed primary growth a coarser one of the same dimensions throughout and much more conspicuous, and that both must be used frequently when once resorted to. The third method is epilation. The latter objection is not applicable to this process, for if the hairs are pulled out "by the roots," which may be easily done, the new growth, which is delayed much longer than after the use of the first two methods, is still tapering, and comparatively delicate. Even this process, by the constant repetition which is necessary to keep the hirsuties under, tends to stimulate to some extent the growth of the neighboring follicles. Yet it is the only one which should be recommended by the surgeon, as within the power of the patient to use or as affording any satisfactory measure of relief, although temporary, without aggravating the deformity against which it is used. For the circumscribed hirsuties connected with papillary and pigment hypertrophy it is, when this is of small extent, a sufficient means of relief. But none of these measures can possibly effect

¹ Read before the Boston Society for Medical Improvement, April 25, 1881.

the desired result, the radical and permanent destruction of the growth, as this can be done only by the obliteration of the hair papilla at the very bottom of the follicle. To accomplish this various methods have been practiced and devised by American dermatologists within the last few years, such as the galvano-cautery applied within the hair follicle; the attempted introduction of powerful caustics or irritants to the interior of the same; the mechanical destruction of the papilla by rimming out the cavity of the follicle with a triangular glover's needle, etc. It may be said of all of them that they are unreliable and therefore unsatisfactory.

It is to Dr. Michel, professor of ophthalmology in the Missouri Medical College, that we are principally indebted for the introduction of a method which is both practical and efficient, namely, electrolysis. Its success was first demonstrated¹ in the treatment of trichiasis, and subsequently its applicability to general hirsuties has been most successfully established, especially by Drs. Hardaway, of St. Louis, and Fox, of New York. The necessary apparatus is a galvanic battery of ten or fifteen cells, supplying a current strong enough to decompose water. An excellent form for the purpose is the chloride of silver battery of sixteen cells, made by the Western Electric Manufacturing Company of New York. It is very compact, free from danger of spilling, and needs refilling only once a year. In addition there is required a small sponge electrode, a supply of the slender steel needles used by dentists for extracting nerves, with a proper electrode needle holder, and two cord conductors of a yard in length. The needle is connected with the negative pole of the battery, the sponge electrode with the positive pole. The needle, secured in its holder, is then to be carefully introduced within the hair follicle to be operated on as far as the papilla, and held there, while with the other hand the moistened sponge electrode is applied to the skin in the immediate vicinity of the part. Immediately a frothy material is seen to ooze from the mouth of the follicle around the needle, the products of decomposition of the tissues in contact with its point. This should be allowed to continue for a few seconds, according to the size of the hair to be destroyed, when the sponge electrode is to be removed, and the needle then withdrawn. The hair should then be removed by forceps, the ease with which it comes away indicating the completeness of the success of the operation. Should this require any force the needle should be again introduced within the empty follicle, and the process of electrolysis repeated. A considerable amount of pain is experienced during the passage of the current through the tissue, which ceases almost entirely on the removal of the sponge. Sometimes, in addition to the frothing, the skin surrounding the needle is thrown up into an urticarial elevation, and is greatly reddened. Later the follicle may become inflamed, and form a crust, which adheres to the skin above it for a week or more. Sometimes a hard infiltration may be felt beneath the surface for a considerable time. Ordinarily the after-effects are very trivial, unless a small area be acted on repeatedly at short intervals. Finally, the parts return to their natural condition, leaving in some instances a minute pit or depression to indicate the seat of the operation. If successful the hair does not reappear. The degree of success depends largely upon the skill of the operator. Dr. Michel claims that ninety per cent. of the larger hairs are at

once and permanently destroyed. Others are satisfied if fifty per cent. are successfully dealt with on the first attempt. The operation needs only to be repeated upon those which reappear until all are finally destroyed. It is a question whether the hair should be extracted before inserting the needle. Where the hair is very coarse, so that the mouth of the follicle is well defined after its extraction, it may be well to remove it before inserting the needle, but when the hairs are fine and blonde their presence is necessary to guide the needle within the follicle to be destroyed. It is easy to make the fine, pointed needle enter the follicle even when the hair remains, and the skilled touch recognizes at once when it has been successfully inserted. Even when the needle cannot be introduced directly within the canal, its point may be made to penetrate the tissues in the immediate vicinity of the papilla, so that the electrolytic action may extend to and destroy this essential point. The subsequent non-resistance to the forceps during extraction shows whether this result has been attained. The patient should be placed in the strongest light, and even under the most favorable conditions the eyes of the operator will tire after a session of an hour or less. Perhaps forty or fifty hairs are all that can be attempted by him at one time with advantage to himself or the patient, although the latter generally bears the pain of the process without flinching after the first few sittings. When an extensive hirsuties is to be treated a long time is required for the successful primary removal of the hairs, and some of the follicles will, without fail, require a repetition of the operation. For the fine, downy hairs occurring alone or interspersed with a stronger growth nothing had better be done until they attain a more conspicuous development.

RECENT PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M. D.

RESECTION OF THE KNEE IN ITS APPLICATION TO THE TREATMENT OF ANGULAR ANCHYLOSIS.²

POINSAT states that in France this operation has not been in favor chiefly on account of the successful results of *redressement forcé* and the influence of the authority of Bonnet.

Although forcible straightening is effectual in a large number of cases, it is useless in bony ankylosis, and injurious (in the opinion of the writer) after purulent inflammation of the knee. A fracture of the fatty degenerated bone frequently occurs, and, though the result is often a useful limb (Nussbaum, Billroth, Rizzoli), in a few cases rupture of the vessels, injury of the nerve, and unfortunate results have followed.

Poinsat regards *redressement forcé* as contraindicated also in ankylosis in young persons, where hypertrophy of the condyles usually follows the subluxation of the femur backwards, which frees the femur from pressure.

In these cases two operative procedures are to be considered, osteotomy of the femur and resection. Of these the writer believes resection to be preferable, for the reason that in this operation the joint is opened and all diseased tissue is removed, and the possibility of subsequent inflammation is removed. The writer

¹ St. Louis Clinical Record, October, 1875.

² Bull. et. Mem. de la Société de Mèd., vol. v., p. 461.

has collected seventy-seven cases, and found a mortality from the operation of eight per cent. The results where antiseptic precautions were employed were more favorable (thirty-six operations and no death).

The writer regards the operation as entirely free from danger in patients under fifteen years of age, but success has been obtained in adults. Six cures are reported between forty and fifty years, and one fifty-seven years old.

CONGENITAL DEFORMITY OF THE LOWER EXTREMITIES, CURED BY RESECTION OF THE KNEES.¹

In a child twenty months old, besides congenital deformity of the fingers, a distortion of the lower limbs existed, so that the toes touched the scrotum. The femora were of normal length. In the right limb the patella and the tibia were wanting, the head of the fibula was driven forward and upward, straightening of the limb was impossible on account of adhesions in the abnormal position. The tibia was slightly curved. The muscles were normal. In the left limb the patella was present, but the upper third of the tibia was wanting. Resection of one knee was performed (under antiseptic precautions). Healing by first intention followed, and in twenty days the second knee was operated on, and the wound healed in twenty days. In a few months the patient became able to walk using apparatus. Ankylosis at the knees did not result, flexion and extension being possible, lateral motion was prevented by supports. Partial development of the rudimentary tibiae followed.

ARTHRITE PLASTIQUE ANKYLOSANTE DE GENOU.²

Nicaise describes an affection which he claims has been overlooked by the majority of surgeons and surgical writers. The name of plastic arthritis was given by Gosselin, and owing to the usual termination the term "ankylosante" is added. In the case reported the affection began with a chill after confinement, the first local symptom was pain in the shoulder and knee, the former soon became well, but the latter entered into a painful chronic condition, which after five months terminated in a stiffness.

This affection resembles, in its result, gonorrhoeal rheumatism, but pathologically it is distinct, as it is present in patients who are not suffering from gonorrhoea. Seven of these cases have been observed: four by Nicaise, two by Gosselin, and one by Duret. The joints affected were the knee four times, the elbow twice, and the hip once. The course is rapid subacute, and the termination is always ankylosis. The treatment should consist in placing the limb in a good position, and in counter irritants, leeches and blisters, to relieve the local tenderness. Whether fixation should be employed or not is at present undetermined, and the writer inclines to recommend gentle passive motion when no pain is caused in that way. *Trisement forcé* is not useful in this affection, but massage may be of some benefit.

ACUTE ARTHRITIS IN INFANTS.³

Mr. Thomas Smith called attention to an affection, frequently fatal, which he termed "acute arthritis of infants," consisting essentially of a pathological change

in the articular extremities of the bones. In all cases examined a considerable loss of substance in the end of one of the bones forming the joint occurred. In some of the cases the absorption proceeded from the joint surface toward the deeper parts; in others the destruction had begun in an abscess at the articular end of the bone, which burst into the joint by an opening near the margin of the articular cartilage. The disease has neither a traumatic nor a syphilitic origin. Mr. W. Marrant Baker reports two additional cases occurring in children six months and nine weeks old. In both effusion within the capsule of the knee took place (in one with suppuration), which was evacuated by incision. The result was great relief from pain, and in one case recovery, with the reestablishment of motion; in the other with marked improvement in position and strength of the limb.

ANTISEPTIC RESECTION OF JOINTS.

König, at the last Congress of German Surgeons, stated that 21.5 per cent. of the cases of resection done by him (117 in all) had become in the course of four years tuberculous, and he concluded that resection had little influence on the tuberculous diathesis, since, according to Billroth's statistics, twenty-seven per cent. of the cases with tuberculosis of the joints not operated on died. In this opinion of König Es-march concurs. But Hueter, Volkmann, and others, dispute this, and claim that there is a fallacy in these figures, as the comparison is between the lightest variety of this class of cases with the severest. Rydygier⁴ claims that the tuberculous affections of the joint occur in three classes of patients:—

- (1.) Those with general tuberculosis, with several local manifestations.
- (2.) Those with primary tuberculous foci in other organs and a secondary manifestation in the joint.
- (3.) Primary articular tuberculosis, from which there is a danger of secondary general infection.

Hence, theoretically, the sooner this focus is removed the less is the danger of generalization of the affection, but operative interference in the first two of these classes cannot be looked upon as a prophylactic measure. In affections of the third class, however, resection should be looked upon as a means of prophylaxis.

SCROFULOUS DISEASES OF JOINTS COMPLICATING PHTHISIS.

In the Transactions of the Medical Association of Georgia, Atlanta, 1880, Dr. Robert Battey reports the following case: A young man, twenty years old, presented signs of consolidation of the left lung, and in the upper part a large cavity. For nearly a year he had been suffering from a suppurating inflammation of the left knee. Amputation of the thigh was performed to relieve him of his pain. His appetite immediately returned, and in a month he became able to go out with crutches. A year later his cough had disappeared, he had grown fat, and became well enough to engage in his occupation. He remained in this condition for three years, when he suddenly died of hæmorrhage from the lungs.

The marked improvement in the patient's condition following amputation illustrates the relation between the original focus and the secondary condition as well.⁵

ACUTE PRIMARY SYNOVITIS OF THE HIP.

Three cases of this affection, hitherto regarded as rare, are reported by Dr. V. P. Gibney.¹ The course run was comparatively brief.

The writer claims that the history of synovitis differs from that of osteitis in that the invasion of the former is acute and well defined. In the early stages of osteitis there is no joint-tenderness, and the pain does not prevent the patient from walking. The reverse is, however, true in synovitis, which is also an acute affection, usually running a course of from four to ten weeks. A diagnosis will often necessarily be based on the exclusion of other affections.

If the joint is tender in synovitis the pain is referred to the obturator whenever the joint surfaces are approximated. There is no infiltration of the periarticular tissues. Sometimes an elastic fullness about the trochanter or below the groin can be perceived if there is much distention of the capsular ligament.

The patients make a good recovery, with reëstablishment of motion. The treatment consists of rest and counter irritation.

HYGIENIC TREATMENT OF RICKETS.

The Pathological Society of London devoted much time to a discussion of the etiology and pathology of rickets, and a variety of theories as to causation were brought up. The most rational of these is that of Broca, who defined rickets as the "ultimate effects of everything which interferes with the nutritive processes during the rapid growth of infancy."

The connection between syphilis and rickets, claimed by some writers, is based on the improvement in certain cases from the treatment by small doses of biiodide of mercury, but this simply illustrates that syphilis may be a cause of the perversion of nutrition, but not necessarily the only cause. English and American authorities lay more stress upon improper feeding as a principle of causation than the Germans, who consider the defect one of assimilation rather than alimentation, and who regard defective ventilation and overcrowding more injurious than faulty diet.

The prevalence of rickets on the Continent, among the poorer classes, is well known. In Milan thirteen per cent. of the children from the poorer quarters suffer from rickets. In Turin four schools have been opened, accommodating thirteen hundred children. The object is to cure the rickety condition by physical development. The children live at home, but are brought to the institutions in the morning, and are taken away at night. The time during the day is spent in instruction according to the kindergarten method. "Every available resource of gymnastics, hydropathy, and orthopædies is employed." The children are fed, and arrangements are made for them to rest during the day. Spirometric and dynamometric observations are made monthly, and the improvement in the deformity is recorded by photographs. Of one hundred and ninety-seven children admitted in one year, thirty-eight were discharged cured, and seventy-eight were greatly improved. Dr. Gamba, the physician in charge, reports that repeated exercise of the muscles aids the absorption of enlarged portions of the bones to which they are attached, and that exostoses disappear. The children admitted are between the ages of four and twelve. A somewhat similar institution exists at Milan, where a few hospital beds are furnished for cases requiring osteotomy.²

FLAT FOOT IN INFANTS.

Volkman³ classifies flat foot occurring in young children under three heads: (1.) Congenital, dependent upon uterine pressure. (2.) A form due to too rapid change into the position of the adult foot. (3.) Rachitic flat foot, appearing sometimes before child begins to stand. (4.) Paralytic flat foot.

C. Hueter is of the opinion that the alteration of the shape of the foot from the slight supination seen in a new-born child into that seen in the adult is the result of the pressure due to the weight of the body. The axis of the astragalo-calcaneal joint is so placed that the weight of the body in walking tends to evert the foot. Volkman rejects the idea that this fact is the cause of the flat foot of children, for the reason that this eversion takes place before children learn to stand, and in the first months of life the foot may be in a position more pronated than is normally seen in adults, and he concludes that under ordinary circumstances the weight of the body in walking and standing has nothing to do with this change of shape of the foot.

In newly-born infants the bones have a different shape from that of adults, and the changes which occur during growth are independent of static laws. As an example of changes in the growth of the limb which take place in opposition to the effect from the weight of the body, the increase in the angle of the neck of the femur with the shaft may be quoted, and also the hollowing out of the arch of the foot. There is, however, a form of flat foot which has been termed "static flat foot," where, in addition to the eversion, a sinking of the arch is to be seen. This change is distinct from that which causes eversion, and which is dependent upon similar influences to those which, working in another direction, prevent in talipes varus and equino varus the partially corrected deformity from remaining without relapse if the acts of standing and walking alone be relied upon.⁴

Holl⁵ states that the deformities of the foot can be classified as follows:—

(1.) Undue development of normal prolongations of the bone. (2.) Abnormal tuberosities not of pathological origin. (3.) The same, but of pathological origin. (4.) An abnormal number of the bones of the feet. (5.) Absence or the coalition of certain bones of the feet, either as a result of a pathological change or congenital deformity. The writer reports two cases of congenital tarsal union: first, of the scaphoid with the os calcis; second, of the scaphoid with the cuneiform bone, resulting from an inflammatory process. In the former the foot was held in the position of a severe flat foot, and in the latter that of a light grade of that deformity. Later investigations⁶ lead him to believe that congenital union and malformations of the tarsal bones are more important in causing flat foot than has been supposed. Four specimens in the Vienna Anatomical Institute with congenital union of the os calcis with the scaphoid show marked deformity of the valgus variety, and others are recorded showing union of the scaphoid and the astragalus. From the specimens he has examined he concludes that a new variety of valgus must be considered, valgus e coalitione, a variety

which it may be perhaps possible to recognize during life, and which is, of course, incurable.

The Report of the Orthopædic Department of St. George's Hospital by Mr. Haward publishes some interesting statistics. Sixty-five per cent. of the cases of flat foot occurred between the ages of fifteen and twenty years. Sixty-four per cent. of spontaneous lateral curvature were between the ages of fifteen and twenty years. Seventy-four per cent. of patients with genu valgum were in children between three and five, and the majority showed other signs of rickets. In a case of antero-posterior curvature of both tibia a satisfactory result was obtained by a wedge-shaped section of bone.¹

CONGENITAL MALFORMATION OF THE SPINAL COLUMN.

Mr. Willett, in the *Medico-Chirurgical Transactions*, describes this rare deformity. The dorsal spine was altered by a slight anterior with a left lateral curve; four and a half of the dorsal vertebrae were missing, five ribs on the right side and four on the left were absent, the left clavicle was out of shape, and the scapula was connected by a bridge of bone with the sixth cervical vertebra. The deformity is, in the opinion of the writer, due to an early defect in the elements forming the vertebral and lateral plates in the embryo.

This malformation was found in an adult woman who had given birth to a living child, and who died of pericardial effusion in her thirty-first year. The specimen is almost unique occurring in a person of this age, a list of specimens in the English museums giving only one other similar case in an adult, sixty-four years old.

WEAK SPINES IN YOUNG GIRLS.

Keating² calls attention to that class of spinal troubles due to strain of position, which is insidious in its onset, and therefore apt to escape attention. The series of cases he divides under two heads:—

(1.) Those young enough to go to school, where the routine is injurious to them, and where cure is to be effected by a proper division of study and recreation, including muscular exercise, good food, and fresh air.

(2.) Those who have drawn from their stock of muscular or nerve force in the development of their intellect. After freedom from the restraint of school, their time is devoted to a sedentary life or to one of undue nervous excitement. In such cases the great muscles of the back are those most called upon, and give out either from want of nutrition or excessive tension. The equilibrium which is maintained by concerted action of the muscles of each side is lost, and neuralgic pains and backache follow. In several cases the writer has noticed a slight impairment of the faradic contractility of the muscles on the convex or weaker side.

He advises as a system of treatment the daily use of the faradic current, applied to those muscles that it is proposed to strengthen, that is, on the convexity of the curve. Cold sponging, friction, massage, light gymnastic exercises, and, if the patient's strength permits, light exercise, and the application of a light support made of card board, wet and moulded to the back, and secured by a bandage, and worn at times, are to be included in the treatment.

LATERAL CURVATURE.

Dr. N. M. Shaffer,³ in discussing the vexed problem of the ætiology of lateral curvature, admitting that the primary causes are not definitely known, claims that certain facts are sufficiently established for consideration, namely: Lateral curvature develops most frequently between twelve and eighteen years, is more frequent in females than males, and occurs more commonly on the right side than the left. A "nervous," emotional, or hysterical condition frequently accompanies the affection. None of these factors are, however, always present, and simple difference in the length of the lower limbs cannot be said to be influential in causing true rotary lateral curvature. The osseous malformation which is found is probably secondary to the original lesion, and the muscular contraction seen is in no way similar to the reflex muscular spasm seen in joint affections. The distortion is probably due to disturbed muscular conditions involving impaired muscular power on one side. The muscles primarily affected are probably not the external muscles moving the spinal column, but the internal group which pass from vertebra to vertebra, and act on the column in segments. An analogue of lateral curvature is to be seen in true torticollis.

The writer makes a distinction between true rotary lateral curvature and that due to simple muscular weakness, in the latter no rotation being present. A loss of lateral flexibility, due to "intrinsic" muscular resistance, is present in true scoliosis, and also frequently a unilateral atrophy of the mamma and unusual position of the scapula. Atrophy of the mamma, however, does not occur in scoliosis below the eighth or ninth dorsal.

Hospital Practice and Clinical Memoranda.

GASTRORRHAGIA AND HÆMATEMESIS, WITH A CASE.

BY E. L. WARREN, M. D., MEDFORD.

HÆMORRHAGE into and vomiting blood from the stomach is a complaint or a symptom which presents many points of interest and importance.

The term hæmatemesis does not necessarily imply hæmorrhage from the stomach, nor does it always accompany such hæmorrhages, as we may have hæmatemesis from other causes without the stomach being primarily affected.

On the other hand, gastrorrhagia may occur without hæmatemesis, and the blood, instead of being vomited, be carried into the intestinal canal, and be defected in the stools. The cause of gastrorrhagia may be: (1.) Direct injury to the gastric vessels by means of wounds, such as punctures by sharp bodies which have been swallowed, or by means of corrosive substances. (2.) By disease of the walls of vessels, as in varices, aneurisms of large arteries, which are in the neighborhood and which become adherent to the walls of the stomach and perforate them. (3.) Venous stasis, leading to a passing through of the red corpuscles or to rupture of the capillaries, with extravasation of blood upon the surface of the organ, causing obstruction of portal circulation; hence we get hæmorrhage from the stomach from cirrhosis of the liver. Gastric hæmorrhage

may occur in cases of hæmorrhagic diathesis, in connection with an excess of blood, and a diminished proportion of its fibrin. (4.) Gastrorrhagia may occur in scorbutus, yellow fever, etc., due, according to Professor Leube, Ziemssen's *Cyclopadia*, Volume VII., "to the qualitative alterations of the blood itself, without any secondary mal-nutrition of the wall of the vessel."

Idiopathic hæmatemesis, independent of any change of texture, is considered rare, and not in any way analogous to epistaxis so common in children.

Vicarious hæmatemesis, occurring with other constitutional hæmorrhages or as vicarious menstruation, is quite common. The female sex seems to suffer from hæmatemesis more frequently than the male. The proportion, according to Handfield Jones, is seventy-four per cent. females to twenty-six per cent. males. It may occur at any age. It sometimes seems to take place spontaneously, but really is due to some exciting cause, which in itself is insufficient to produce hæmorrhage in a sound gastric membrane, but able to elicit a rupture when any tendency to hæmorrhage already exists.

Under this head can be mentioned mental excitement, strains, concussions of the body, and over distensions of the stomach.

When a large enough quantity of blood is poured into the stomach, from whatever cause, it gives rise to a nauseating effect sufficient to produce vomiting, and is thrown up almost always in considerable quantity, and of a dark color, while that which is coughed up is most frequently bright. The color is changed by the action of the gastric juice. The hæmoglobin is changed to hæmatin. After the loss of blood has been considerable the patient presents the usual symptoms of anæmia, pallor, coolness of extremities, giddiness, and fainting.

Although a correct diagnosis can readily be made out when the amount of vomitus is quite profuse, especially when one has an opportunity of witnessing the attack, yet in some cases it will be quite difficult to ascertain whether the blood was vomited or coughed up, whether it came direct from the stomach or the adjacent parts.

When called, therefore, to the bedside of a patient, it is of importance to decide whether the reddish-black fluid vomited is really blood. A microscopic examination is sufficient usually to remove all doubts by the discovery of blood globules. In a great majority of cases it is merely symptomatic, and the nature and seat of the disease, of which the bleeding is a symptom, may be most commonly determined.

Of the prognosis, Professor Leube says, "a comparatively large number of patients with hæmatemesis recover from the most hopeless anæmic states, and we should not therefore despair of saving the patient until death has actually taken place. Still the loss of blood is, under all circumstances, a depressing factor, and it should never be forgotten that one of the chief dangers of hæmatemesis arises from the tendency of the fundamental disease to induce a recurrence of the attack."

"Hæmorrhage produced by the erosion of large vessels is of course especially dangerous, while the vicarious hæmorrhages, dependent upon capillary congestion, are usually of a harmless character."

The treatment to be adopted, after considering the many different morbid conditions upon which it may depend, is to be directed against the disease of which

the hamatemesis is a symptom, and not against the symptom itself. If it is occasioned by poisoning, the proper antidotes against further injury to the blood-vessels should be used. If from cirrhosis of the liver, local depletion and cathartics may be of service. If from chlorosis, give preparations of iron and the hygienic treatment of an anti-scorbutic nature. Anything that has a tendency to increase the force of the heart's action, and heighten the blood pressure in the vessels of the stomach, should be strictly avoided, and therefore the most perfect rest in the recumbent position required.

The intense alarm of the patient caused by the occurrence of vomiting blood should be allayed by assuring words, and care should be taken to avoid any local irritation of the mucous membrane of the stomach by hot drinks, highly seasoned articles of food, or coarse diet. The safest plan is to give only bland liquid nourishment.

The question may naturally arise whether we have any remedies which will, with certainty, control dangerous hemorrhages. If so which one is to be chosen as giving the most promise of rendering effectual aid in case of emergency.

The best hamostatic, and one of the most efficacious, is cold, administered in the form of the ice pill, in connection with the external application of ice to the epigastrium. The ice pill allays extreme thirst, and helps to stop the tendency to vomit.

In the hemorrhagic diathesis, when we may suspect a diminished proportion of fibrin, any known remedy which will help to restore the contractile action of the capillaries already weakened, will be of great service.

The following case will serve to illustrate some points of interest in connection with this brief review of the aetiology, symptomatology, diagnosis, and treatment of gastrorrhagia and hamatemesis:—

Miss C. B., aged twenty-five, single, weight one hundred and twenty-five, living with her parents, who are both healthy. She has been a public school teacher for four or five years, and is now a teacher; is accustomed to sufficient amount of out-door exercise, as she walks from her home to school, three quarters of a mile away, daily; has no hereditary predisposition to any disease; always considered herself healthy in every respect.

She never complained of any illness of any kind worth mentioning, till some time in October last, when she was troubled with what she thought dyspepsia, and took the usual remedies, but without any benefit. Previous to, and whilst complaining of dyspepsia she had been taking lessons in singing by the Abdominal Method or Elocution Breathing. She took her lessons weekly, and of one hour's duration. Soon after taking a few lessons she felt a severe distress at her stomach, "a deathly feeling" as she termed it, and said, that the singing made her dyspepsia worse, and, in fact, made her feel so badly as to incapacitate her at times from finishing her lesson.

After a month or so, she discontinued taking lessons for about the same length of time.

She again commenced them, and after each lesson the return of the same distressed feeling was experienced. The last lesson was taken February 12, 1881. Sunday evening, February 13th, just before retiring, she felt a very great distress, and soon vomited a pint or more of dark bloody fluid. Early Monday morning, February 14th, vomited again, about the same quantity

and of the same character. She went to school at the usual time, and while there again vomited. There was no recurrence of hæmorrhage until the afternoon of Wednesday, February 16th, when she again vomited perhaps a quart of a similar bloody fluid, at which time I was called and saw her just after she had ceased; from the loss of blood, and the extreme fright consequent upon the same, found her almost pulseless, with cold extremities, blanched lips and cheeks, and almost in a state of collapse.

The treatment consisted in quieting her fears as far as possible. Mustard was applied to epigastrium, hot water to feet, and fl. ext. ergot and pyro-gallic acid in muc. g. acacia were to be given, and repeated directly after vomiting. The recumbent position was strictly enjoined. I saw her again in the evening of the same day, and then learned the history of the case as above described. I then carefully examined the case in detail; and in answer to strict inquiries in regard to her previous health she informed me that she never had been sick enough to call a physician since childhood, had no trouble with the functions of menstruation (was having her menses at the time), was not subject to epistaxis, never had any trouble with the liver or spleen, heart or lungs, never was subject to a cough except for a slight cold. She never had had any malarial trouble, and in fact had always considered herself well; and as far as an examination of all the organs, above referred to went, they seemed to be in a perfectly normal condition. The diagnosis of the case was not clear, and I felt in doubt as to the cause of the hæmorrhage till she informed me, rather inadvertently, that she had been taking lessons in the new mode of singing. The true cause of the trouble at once seemed more apparent, and in the absence of all other known reasons or recognized causes I was disposed to adopt the opinion that the hæmorrhage resulted from the injurious effect of the singing.

This case is most certainly not devoid of interest to the profession and to the community, occurring, as it does, so soon after the cases in the practice of Dr. Clifton E. Wing, reported in the Boston Medical and Surgical Journal, November 25, 1881. The cause seems the same, although the results differ. Dr. S. W. Langmaid, in answer to inquiries made by Dr. Wing, said, "I have no doubt that injuries such as you describe have been produced by attempts at abdominal (diaphragmatic) respiration. I have known the digestive functions disturbed, pain and soreness in various parts of the abdomen produced," etc.

I will not quote further; suffice it to say, that in the opinion of the above named physicians injurious pressure may come upon the internal organs, causing various forms of trouble, especially in females, as the result of this new method of singing. Now in carefully investigated cases other effects of like character may be found, and this should render the subject worthy the attention of the family physician.

February 17th. Patient rested during the night. Pulse 103. Tongue slightly coated. Some thirst. No appetite. To continue treatment of ergot and pyro-gallic acid.

February 19th. Had a comparatively comfortable night. To be kept perfectly still and free from excitement.

February 20th. Recurrence of hæmorrhage again this morning. Pulse 100, feeble. Tongue coated in centre, very thirsty, pale, and anæmic, extremities

warm. Vomited about a pint of bloody fluid, dark colored, not coagulated.

Dr. Hodgdon, of Arlington, saw patient with me in consultation at twelve o'clock. After a very careful examination he, in the absence of all negative symptoms, fully acceded with me in my diagnosis of the case, although at first rather in doubt as to the cause, which in my opinion was the direct factor in bringing on the hæmorrhage. Dr. Hodgdon took a specimen of the bloody fluid for examination by the microscope.

February 21st. General appearance favorable. More color in face. Pulse 106. Temperature 99° F. Tongue slightly coated, but moist. Thirst gone. Slept quietly all night. Dejection from the bowels.

February 22d. Passed a comfortable night. Temperature normal. Tongue moist, and no distress or pain.

February 23d. Is feeling better this morning. More color in face and lips. Pulse 100. Tongue nearly clean.

February 24th. Had a good night. Says she feels better than for some time. Pulse 90. Tongue clean. Decidedly more color in face.

In the evening at about seven o'clock, while being assisted to an upright position upon the stool felt "a death-like" sickness, lost consciousness and fell backwards. In about twenty minutes after getting again in bed she had a return of the vomiting, in quantity perhaps a half pint, and as nearly as I could judge half blood, of a bright red color, and of fresh appearance. I saw her about eight o'clock, and during visit she vomited the second time, less in quantity, character of vomitus the same. At about nine o'clock she vomited again, in quantity about the same but of a dark color.

No return of hæmorrhage during the night, and at the morning visit, February 25th, I found her quite comfortable, she rested somewhat, but the thought of again bleeding had prevented her from enjoying quiet sleep. Pulse 100. Temperature 99° F.

Treatment, ice to epigastrium.

Ice pills to be taken quite often, pulv. opii and ipecac at bed-time, and to continue ergot and acid, especially after vomiting.

February 26th. No return of vomiting. Slept during night. Pulse 106. Temperature 100° F. No pain or distress.

February 27th. Pulse 100. Temperature 99° F. Tongue slightly coated. "Says she has a very disagreeable sweetish taste in mouth." To have tr. chl. ferri gtts. xv. in sat. sol. cld. potass, 5ss three times per day, and to continue opii and ipecac, omit ergot and acid.

Microscopical examination by Dr. Hodgdon of the fluid vomited gave conclusive evidence of blood globules, the relative proportion of red and white was maintained.

February 28th. Pulse 92. Temperature 99° F. Had a quiet night and is feeling quite well. Some appetite for such things as are forbidden.

March 1st. She has now passed a week, and no return of hæmorrhage; is much better. Pulse 92. Tongue clean.

March 3d. Slept well all night and is anxious to get up.

After-treatment to consist in guarding against the recurrence of hæmorrhage. To spare the stomach, by using only easily digested articles of food, and a gradual and cautious return to her usual diet.

March 5th. Doing well, and feeling a great desire

to get up. Pulse 88. Natural appetite returning. Bowels moved by injection.

March 9th. Sat up to day about twenty minutes without any bad effects, except feeling a little dizzy. Taking some food, and digests it without pain or distress.

March 11th. Sat up yesterday and to-day, about twenty minutes each time, but feeling rather weak. To have quinae sulph., grs. ii., two or three times per day.

March 13th. Sat up to-day three hours, and is feeling quite well and will soon be convalescent.

A GALLSTONE.

BY WILLIAM HERBERT ROLLINS.

PATIENT a previously healthy woman of sixty years. From August 12th to August 19th "sick headache" at intervals.

August 19th. Took two Schenk's pills. There was a slight operation, the last till August 27th.

August 20th. Took one Schenk's pill.

August 21st. Remained in bed, which she did not leave for fifteen days. Complained of severe paroxysmal pain above the navel; the pain continuing during the day and night.

August 23d. Took ten grammes of castor oil and an injection of soap and water. Vomiting began during the morning following each paroxysm of pain and continued at intervals of ten to fifteen minutes until August 24th, at nine p. m.

August 24th. The patient was seen about five p. m. Condition at this time: Face haggard, she was lying on her back, thighs flexed, and legs drawn up, but no position was long maintained, though the thighs were pretty constantly flexed. Abdomen slightly sensitive and a little distended. Tongue, dark and dry. Pulse 115, irregularly intermittent. Temperature 104° F. Paroxysms of pain, lasting from three to five minutes, came on at intervals of from seven to ten minutes, followed by vomiting of yellowish fetid fluid. Chloroform was given at the approach of each pain till nine p. m., then twenty-five milligrammes of sulphate of morphia were injected into the arm, the injection being repeated four times during the night. Vomiting and pain, which had grown less since the first administration of chloroform, ceased at ten p. m. to return no more.

August 26th. As the patient could not sleep an opiate was given at intervals till September 1st. To avoid the constipating action of morphia on the bowels narcia was used in twenty milligramme doses. It was rubbed dry upon the tongue to prevent deranging the stomach.

August 27th. An involuntary discharge of black liquid and putrid feces. The first operation in eight days. Nothing was recognized but some pieces of peach skin. Similar discharges continued at intervals during the following day.

August 29th. On this night a discharge of greater consistency occurred. In it was found a hard lobulated egg-shaped body measuring 4.40 by 3.40 centimetres, and weighing one hour after it was passed 11.950 grammes.

The body was easily divided by a saw. There was a nucleus one centimetre in diameter, of a gray-brown color. A light yellow band surrounded this, sending

radiating prolongations to the surface of the mass, through the enveloping dark brown material. Ether dissolved most of the sawdust. The solution was without color. It yielded colorless tabular crystals with angles of $100^{\circ} 30''$ and $79^{\circ} 30''$.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

APRIL 25, 1881. DR. T. B. CURTIS presided.

CHRONIC ENDARTERITIS OF THE AORTA, WITH UNUSUAL COURSE AND CONSEQUENCES.

DR. DRAPER exhibited the aortic arch from the body of a woman fifty-five years old, and presented brief notes of the clinical history of the case. Symptoms referable to the disease represented by the specimen began to develop in 1875, when the patient first had severe shooting pains in the left side of the neck, and between her shoulders; these were attended with dyspnoea, sometimes amounting to orthopnoea, symptoms which persisted during her life. At intervals of two or three months, between 1875 and 1879, she had attacks, which she described as "spells coming without warning, seeming as if a wave struck her on the back, rolled up over her shoulder, and broke as it crossed her head." During these nervous paroxysms her urine became dark-colored, and micturition was painful; the attacks ended in insensibility, the patient falling wherever she might happen to be.

In 1876, her attending physician, Dr. W. H. Campbell, of Roxbury, observed a slight fullness above and below the sternal end of the left clavicle; he detected some pulsation at this point, and a sound which he interpreted as an aneurismal bruit. At this time, also, there was a very perceptible difference between the two radial arteries, the impulse in the right being normal, that in the left being soft and small. Nothing wrong was observed about the heart.

In August, 1879, the patient was found, one evening, in an unconscious condition on the street, and was thereupon admitted to the City Hospital, where she was under Dr. Draper's observation for six weeks. At this time the prominence over the clavicle was not apparent. The left radial pulse was relatively much weaker than the right, and at times was wholly obliterated. The left carotid pulse was also scarcely perceptible. The voice was tremulous, and at times husky. The pupils were equal, although the patient stated that she had noticed a dilatation of the left pupil coincidently with the attacks of pain and dyspnoea. A musical murmur was heard above the middle of the left clavicle over a limited area. Nothing wrong was noticed about the heart. Under treatment the patient grew stronger, and her general condition improved; the oedema of the feet and ankles, somewhat annoying at the time of admission, subsided; the souffle above the clavicle was less distinct. Pain in the left arm developed during the latter part of her stay, but there was no change in the appearance of the arm. While a patient at the hospital she had no recurrence of the neurotic attack.

During the eighteen months after her discharge from the hospital, and up to a few days before her

death, she was able to live in comparative comfort most of the time. An occasional exacerbation of her previous symptoms occurred. Dr. Campbell noticed in the autumn of 1879 that the musical sound had wholly disappeared from above the clavicle, and the left radial pulse was lost. The pain in the arm continued. A fortnight before her death she had an attack simulating angina pectoris. She was found dead in her bed one morning, having retired in usual health the night previous.

At the autopsy the chief interest was found to centre in the heart and arch of the aorta. The heart was hypertrophied to a marked degree, and there was a moderate amount of dilatation of the left ventricle. The muscular tissue was of good color and firmness. All the valves were normal except the aortic, whose semi-lunar folds were thickened, retracted, and irregular, constituting a stenosis as well as incompetence of the aortic opening. The coronary arteries were healthy. The aorta throughout its extent was thickened, roughened, and reduced in calibre. Thin plates of calcareous matter were imbedded at intervals in the intima. But the most interesting feature was the fact that in the process of inflammation and consequent alteration in the coats of the artery, the orifice of the left common carotid had become wholly occluded by a semi-transparent tissue thrown across it, and presenting on the inner (aortic) side a small funnel-shaped depression, while the orifice of the left subclavian was in a similar manner almost obliterated, the opening for the passage of blood being reduced to a mere point, admitting a fine probe. Both the arteries (carotid and subclavian) above this obstruction were of normal size, and their walls were, apparently, a little thinner than usual. The innominate, on the other hand, was dilated so as to admit the tip of the index finger to the distance of nearly an inch; its intima in this dilated portion shared in the inflammatory process of the aorta. Above this part the innominate was normal. Other organs and regions of the body presented nothing noteworthy so far as they were examined. The head was not opened.

HIRSUTIES.

DR. WHITE made some remarks on the use of electrolysis in the treatment of hirsuties, and exhibited a battery adapted for this purpose. Vide page 412 of the JOURNAL.

LITHOTRITY.

DR. FRANCIS WILLIAMS, by invitation, described and exhibited a new evacuator for the bladder, the report of which will appear in a later number of the JOURNAL.

DR. BOLLES thought that the valve, which seemed to him similar in principle to that of the "flute-key" valve of a stomach pump, might be used with advantage in connection with a siphon for filling, emptying, or washing the stomach without the usual stomach-pump syringe. Its compactness and simplicity would commend it for that purpose, and the readiness with which the current can be reversed makes it more desirable than the siphon alone.

—"Three or four hours daily in the open air regardless of weather, light meals, and plenty of sleep," is the recipe for good health which Bancroft, the venerable historian, freely offers to the public.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

At a stated meeting, April 25th, Dr. Clinton Wagner read a paper on *Habitual Mouth-Breathing: Its Causes, Effects, and Treatment*. He first called attention to the fact that the habit of mouth-breathing, with its attendant evils, was confined to civilized nations, and entirely unknown among the savage races of mankind. Thus, Catlin had found that in one hundred and fifty tribes of North American Indians there was no deafness or disease of the air-passages, and after a careful study of the subject had arrived at the conclusion that this was attributable to the fact that nasal breathing was universally practiced among them. This experience was confirmed by Dr. Wagner's own more limited observations when he was an army surgeon in Idaho. Near the post where he was stationed was a large Indian village, the inhabitants of which were nominally under his professional care, and he had frequent opportunities for noticing the entire exemption of the community from ear, nose, and throat disease. Yet the sanitary conditions in which these people lived were, as a rule, of the most unfavorable character, and there could be no doubt that this immunity was due solely to the total absence of mouth-breathing among them.

The causes of this unfortunate habit, so prevalent in civilized communities, were to be looked for in the nose, mouth, and throat. In regard to the conditions giving rise to it, it had formerly been impossible to arrive at a correct diagnosis in many instances; but with the rhinoscope and other modern appliances at our command, this was no longer the case. Among the nasal causes was mentioned occlusion of the inferior nares, particularly by a deviation of the septum, which might be either congenital or acquired. Sometimes the septum was twisted like the letter S, a condition apt to produce stenosis on both sides. Other sources of mouth-breathing were found in the presence of nasal polypi, mixomata, fibromata, adenomata, exostoses, and false membranes resulting from syphilitic or strumous ulcerations. In some individuals there was a congenital imperforate condition of the nares, and in others there was a general thickening and hypertrophy of the mucous membrane. It was not necessary, however, that the nares should be completely closed. When any of the above pathological conditions existed, even a slight cold in the head would often render nasal breathing exceedingly difficult, and if this were to recur from time to time the pernicious habit of mouth-breathing would gradually be acquired.

Of mouth causes chronically enlarged tonsils constituted the most common. Among the others enumerated were tumors of the soft palate and pharynx, and also elongated uvula. If the latter was present, the patient would soon find by experience that the disagreeable tickling and irritation caused by it were relieved to a great extent by opening the mouth, which always caused more or less retraction of the velum, and with it of the uvula. Irregular, uneven, and imperfect teeth also sometimes give rise to the habit of mouth-breathing.

As to the effects produced by it, they could be at once recognized in any one who had been addicted to it for any considerable time. Among the characteristics plainly stamped upon the countenance of such a one are the retracted lips, the protruding teeth, the

open mouth with the peculiar wrinkles surrounding it, and the silly and almost idiotic expression which the observer could at once recognize. The law of compensation did not apply to the nose as to other organs. Thus, if one eye or one ear were impaired, the sensitiveness of the other became increased, while if one arm was amputated the strength and usefulness of the other was augmented; but the closure of the meatus on one side of the nose did not cause the other one to expand. On the contrary, this one also was apt to become diminished in size. The sense of smell became greatly impaired or was altogether lost, while the whole contour of the nose was changed. The sense of hearing was more or less affected, the relaxation of the muscles controlling the mouth of the Eustachian tube, leaving this continually open; and the trouble varied in different cases from slight to total deafness.

The effects upon the pharynx were readily recognized. The constant action upon the mucous membrane of cold air, which was very apt to be loaded with impurities, resulted in follicular pharyngitis or pharyngitis sicca, one of the most distressing of all throat affections. The patient was forever making efforts to dislodge the hard, dry, tenacious mucus, and so common was this trouble that a continual hawking saluted our ears, whether we were in the cars or at the social gathering, the church or the theatre. Chronic catarrhal laryngitis was also a common result of mouth-breathing; and when a strumous diathesis was present tubercular laryngitis was almost certain to follow. Snoring, too, was due to it, this habit being unknown among those who breathed through the nose.

The effects of mouth-breathing upon the general constitution were very serious, and in young subjects it was apt to result in the malformation of the thorax known as "pigeon-breast," and in imperfect oxygenation of the blood and faulty nutrition. Again, asthma might be produced by closure of the nasal passages from any cause, and nurslings suffering from coryza are sometimes subject to asthmatic attacks during sleep. In some cases, indeed, the tongue had been swallowed under these circumstances, and death had resulted from asphyxia.

Dr. Wagner then went on to speak of the treatment, and said that the local cause was first to be sought for in any case, after which such operation should be performed or topical medication applied as was necessary to remove it. After referring to the operative procedures for correcting the shape of a deviated septum and removing exostoses, polypi, and other forms of tumor, he advocated very strongly the use of dilatation by means of metallic sounds for stenosis of the lower meati from hypertrophy of the mucous membrane over the inferior turbinated bones. In this plan of treatment, which he had found very successful, he had been guided by the same principles which had proved of service in urethral surgery. At first the passage of the instrument proved quite painful in some cases, but not more so than the introduction of the sound into the bladder often proved. This hyperæsthesia passed off after a few applications, however, and the patient generally derived so much relief from the procedure that he was quite willing to have it repeated as often as was necessary. The dilators employed varied in size from that of an ordinary pocket-case probe to that of a No. 6 or 8 urethral sound, and weeks, and sometimes months, were required for the process. For the first week it was best to introduce the instru-

ment daily, but afterwards less often. Patients could also be instructed to practice the dilatation themselves in any case where this was desirable. In addition it was often advisable to make the following application to the mucous membrane:—

R. Iodinii	gr. ij.
Potass. iodidi	gr. iv.
Zinci iodidi	gr. x.
Aque	℥. ʒi.

In the above formula the chloride of zinc (five grains to the ounce) could sometimes be substituted with advantage for the iodide. Where the tissue was excessively hypertrophied the galvano-cautery was recommended.

If the mouth-breathing was due to enlarged tonsils, excision was to be regarded as the only satisfactory remedy, and Dr. Wagner stated that he never made topical applications in such cases except under protest, when urgent objection was made to the use of the knife. The operation, if performed with the guillotine, was very simple, and, in his opinion, wholly devoid of danger. When infants and very young children breathed through the mouth instead of the nose, an examination should be made to find out what the difficulty was. Mothers and nurses, the most careful to keep every other part of the child scrupulously clean, almost universally neglected the nose; and it was recommended that the noses of infants should be cleansed by means of a small syringe and warm water, or a small camel's hair brush. A little vaseline applied at night would prevent hardening of the nasal secretions until the child was old enough to learn to snuff up water with the nostrils from the hand. If the mouth was found open during sleep the lips should be gently pressed together, and all children at an early age should be taught the vital importance of always breathing through the nose instead of the mouth.

Dr. Wagner's paper was discussed by Dr. Andrew H. Smith and others, after which Dr. A. D. Rockwell read a paper entitled *Progressive Locomotor Ataxia Differentiated from Functional Conditions which simulate it*.

Recent Literature.

Students' Aid Series. Aids to Diagnosis. Part I. Semiology. By J. MILNER FOTHERGILL, M. R. C. P. London. 1881. *Part II. Physical.* By J. C. THOROWGOOD, M. D., M. R. C. P. New York: G. P. Putnam's Sons. 1881.

These are two very neat little primers of unusually attractive external appearance. They are primers intended for the medical student, not for the public. In Part I., or *Semeiology*, Dr. Fothergill has essayed to put in a compact form the signs or symptoms which are noted by the eye before a physical examination of the patient is made, and under the same heading are discussed the pulse, the temperature, and the examination of the urine. The author has succeeded in doing this cleverly and entertainingly, and on the whole very successfully.

There can be but one opinion of the importance of this part of medical education, and of the value to the practitioner of the acquisition of an *opticus eruditus*. No one becomes more entirely conscious of this than the physician to out-patients of a hospital in a large city. Though the importance of semeiology is still

recognized in the abstract, it is practically less and less cultivated since the introduction of so many new instruments of precision.

The old-fashioned physician and the country physician of to-day even, with their five senses educated to the highest point and well alive, will often reach conclusions in regard to a given patient which the ophthalmoscope, the sphygmograph, etc., will arrive at with scarcely greater accuracy and with much expenditure of labor and time. The danger, of course, lies in the temptation to "snap" diagnoses and to the exaggeration of certain signs, of which Dr. Fothergill's little compendium affords apt illustrations. Thus the student must be on his guard not to take him too seriously when he reads, under the title *Forehead*: "In some cases the forehead carries with it a moral significance. There is the broad, eburnated forehead, the forehead Jeremiah recognized when he said, 'Thou hast a whore's forehead, thou refusedst to be ashamed.' The woman with this forehead will deny pregnancy with the most unblushing effrontery, and is utterly untruthful when anything connected with morals is involved." And again, under the title *Chin*: "A prominent chin goes with the full underlip and the light morals." Again, under the title *The Ears*: "A wrinkled ear lobe, with a face seamed with wrinkles, usually goes with extensive but very chronic visceral cirrhosis." Under the title *Hands* we find: "Where there are black, sodden 'hang-nails' on the fingers of girls they tell of illicit practices, and so are very instructive. Especially is this the case where there is a cold, wet palm," etc., etc. A too literal interpretation of such passages would, of course, quickly get the student or the young physician into considerable trouble. The little book, as a whole, if followed prudently, contains many serviceable hints, and it is a good attempt to do what in future may be still better done.

The companion primer, on the principles of physical diagnosis, explains in sixty 16mo pages the usual methods practiced for the investigation and diagnosis of diseased states of organs.

Photographic Illustrations of Cutaneous Syphilis. By GEORGE HENRY FOX, A. M., M. D. Forty-eight plates from life. Colored by hand. New York: E. B. Treat, No. 757 Broadway.

The seventh, eighth, and ninth fasciculi of Dr. Fox's atlas are received. We appreciate the author's energy, we wish him well personally, we emphasize the necessity of such works, and we regret the slight measure of success attending the present one. The three parts just issued are inferior to their predecessors in the character of the negatives, and suggest that the stock is running low. The experience gained by the author in the publication of colored artotypes should forbid also the issuing of such half-finished work as this in question. There has been too much good chromolithographing done in this line to allow of contentment with vague and blurred pictures from any source. No. 7 represents tubercular syphiloderma under its simple, ulcerative, squamous, and crustaceous forms. The first is passable, but uncolored, the second is vague as the shades of Ossian's heroes, while its companion piece resembles a circinate erythema as much as it does a syphiloderma; the following plate is good, characteristic, and unmistakable; the concluding one represents the individual lesion well, but everywhere subject and

background are almost smeared, as it were, together. Nothing is clean cut, and even the tuberculo-squamous syphiloderm of the breast is obscured by the "natural quick-set, thick-set hairy cover" of its bearer. As a specimen of hirsuties and folliculitis he is certainly remarkable. No. 8 portrays cases of tubercular, suppurative, ulcerative, and pustulo-crustaceous syphilodermata, and one of scrofuloderma. These, though the artist does not represent loss of substance naturally, are all good, especially the pustulo-crustaceous, which is excellent. There are no black backgrounds here, and the plates gain immensely by their absence. No. 9 gives four cases of syphiloderma gummatusum: the first localized and single and good, the second diffused and pretty good, the subject blurred, the background bad; the third dubious, and suggesting fistulae from necrosis as much as gummata; picture, as a whole, cheap looking; the fourth and last plate represents a rubicund and jovial face of Shakespeare, situated like the old "man of the mountain," upon the knee of a lady evidently addicted to scrubbing floors. We shall not deny that the condition represented is pathologically gummatus, we accept Dr. Fox's statement, of course, but certainly, as far as appearances are concerned, it seems as if a better example of gummous syphiloderma might have been selected.

A word of praise here for Dr. Fox's earnest efforts in the direction of an improved nomenclature in syphilis. He divides the syphilodermata into, practically, two classes: (1) the early disseminate and symmetrical eruptions; (2) the later and non-symmetrical ones. The early he considers as erythematous, papular, pustular; the late as tubercular, pustulo-crustaceous, gummous. The vesicular eruption, very rare, he would place in Class 1. The squamous would be an early scaling papule, or a chronic, scaling, ill-developed tubercle. Under pustulo-crustaceous he includes bulbous eruptions, ecthymas, rupia, etc. All of the eruptions of Class 2 may, of course, be modified, and appear ulcerated or suppurative. Now, this is at all events an attempt at a better system of classification than the lesional one of Willan and Biett, which has been long outgrown. Most certainly, also, "too much stress is laid upon primary lesions."

The Metric System in Medicine, etc. By OSCAR OLD-
BERG, Pharm. D., Medical Purveyor, U. S. M. H. S.,
etc. Philadelphia: P. Blakiston. 1881.

In the work before us Professor Oldberg has attempted to present an easy transition from the use of the duodecimal to the decimal system of weights and measures. We cannot agree with him that the way can be made easier by following his plan, which consists of the employment of "fluigram" for cubic centimetres, "dime" for decigramme, and "cent" for centigramme, and "mill" for milligramme. It would seem in our judgment that the great advantage of the metrical system is for all nations to use the same name and symbols and figures, to represent uniformity in the employment of terms of weight and measure.

Some of our readers may be surprised to learn on page 15 that the Hon. J. K. Upton, Assistant Secretary of the Treasury, says in the concluding paragraphs of his report: "It should be borne in mind that the only legalized system of weights and measures in this country to-day is the metric system, and that this sys-

tem is the only one we possess in harmony with that of any country." We are not surprised that physicians hesitate to use the metric system in prescription writing, if they are compelled to "learn the equivalents of the units of either system in the units of the other by heart; to apply convenient rules of conversion, verifying the results by reliable tables; to use a posological table in which the doses are given in terms of both systems, thus enabling the physician to verify the metric dose by direct comparison with that in apothecaries' weights and measures after correcting or modifying the latter dose by the light of his experience and the requirements of the case in hand; and finally, to examine already prepared metric prescriptions such as afford abundant illustrations of familiar practice."

This may do well enough for the practitioner who carries fifty prescriptions in mind ready fitted for any bedside practice, but it will probably stagger him to go through this calculus, until he has learned them all by heart; and how would it be with the practitioner who applies his therapeutical knowledge to his individual practice, formulating his prescription from a single dose which he brings to bear to combat the symptoms before him? His therapeutical and physiological knowledge will be put to rout before this mathematical calculation suggested by our author.

In our judgment the only way to use the metric system in medicine is to learn the single doses in that system, and the posological table arranged by Professor Oldberg is valuable for this purpose, and is probably the best part of his book. However, if any physician cares to translate his duodecimal prescription into the metric system he can readily do so by applying the eleven rules on pages 20 and 21; for our part we should prefer to apply these rules to the doses we have already learned in grains and drams, and to build up each prescription from the single dose. The seventy-five pages of prescriptions in both apothecaries' and metric weights are interesting curiosities, and it would not take many days to learn these by heart, but we shall leave this trouble to our readers.

The Sympathetic Nerve; Its Relations to Disease. By
C. V. CHARIX, M. D., House Physician Bellevue
Hospital. Providence, 1881. Pp. 92.

This is the Fisk Fund Prize Essay for 1880, and is a very creditable epitome or résumé of what is known upon the subject. There are two or three characteristics which may be noticed. The first is brevity. No unnecessary words are used, indeed, the brevity is carried so far that it requires very close attention to follow the author understandingly. When it is considered that a few years since Vulpius published two volumes, of about six or seven hundred pages each, upon the vaso-motor nerves, this brevity will be better appreciated.

Another characteristic is completeness. The sympathetic is considered in nearly all its relations; the anatomy is very briefly reviewed, then its physiology is given in more detail, and, finally, the pathology of lesions of the sympathetic is treated under appropriate headings. Not only is the completeness of the work shown by the fact that almost every lesion is briefly mentioned, but there has been an exhaustive study of authorities, and the opinions of different observers have been sifted, and are given in very few words.

Again, not the slightest pretense is made to raise

the book above what it really is, a brief, compact, and very useful compendium of our present knowledge in regard to the sympathetic. No ill formed and half-digested theories of the author are advanced to lend to the book an air of originality, but the author modestly keeps himself in the background. For these reasons the book is deserving of commendation, and any one desiring to know what is the present state of information on almost any question in regard to the sympathetic will be likely to find it stated intelligibly in a few words.

The author mentions an experiment in regard to the condition of the blood-vessels during sleep, which is of interest. "Hearing it suggested that if sleep is dependent on cerebral anæmia, any nitrite, which promotes the circulation in the brain, should awaken sleeping persons, I tried it one evening. With the aid of my nurse I very carefully applied a few drops of the drug to the nostrils of ten or twelve patients who were sound asleep, and in every case they awoke in less than one, or at most two, minutes. This was repeated on several evenings, and on different patients, but with a uniform result. Lest it might be the odor of the drug, or its irritation of the fifth nerve, or my presence near the bed, I tried, on other occasions, bisulphide of carbon and oil of peppermint, but succeeded in awakening not a third of those on whom they were employed."

From the closing sentences in regard to trophic nerves it would seem that Dr. Chapin does not accept the view that there are such nerves distinct from vasomotor and sensory nerves.

So condensed is this book, and it is so almost entirely a record of experiments and opinions of others than the author, it is not possible to give an extended review of the facts and theories presented. So far as a careful reading can discover it is correct, and the authors quoted or referred to are not misrepresented. As references are given any one can satisfy himself on this point in regard to any subject in which he is interested.

The Student's Guide to Medical Case-Taking. By FRANCIS WARNER, M. D. Lond., etc. Philadelphia: Presley Blakiston. 1881.

The author of this little book, a 12mo of two hundred pages, held during three years the office of medical registrar to the London Hospital. Impressed, whilst holding that office, with the need of the student of some guide as to what to observe in case-taking, and how to arrange his observations methodically, he offers this volume for the use of the student at the bedside. It is well arranged, and will be found convenient.

A Manual of the Practice of Medicine, designed for the Use of Students and the General Practitioner. By HENRY C. MOTE, M. D. New York. 1881.

This book comprises 150 12mo pages, and treats of every disease which is likely to come under the notice of the practitioner. The author's object has been to present to the student and to the busy practitioner a book in which a single point may be easily looked up, and in which the morbid anatomy, ætiology, symptoms, and treatment of every disease are so arranged that any one disease can be quickly reviewed.

The student will cram, and some practitioners will be very busy, hence books of this class will be pub-

lished. The present volume is certainly very condensed. At the end are to be found about four hundred prescriptions arranged in alphabetical order, according to their therapeutical uses.

A Guide to the Clinical Examination of Patients and the Diagnosis of Disease. By RICHARD HAGEN, M. D., Privat docent to the University of Leipzig. Translated from the second revised and enlarged edition by G. E. GRAMM, M. D. Philadelphia and New York: Boericke and Tafel.

The excuse that there is an absolute necessity for more students' and busy practitioners' guides, aids, reference books, *vade mecum*s, etc., etc., will scarcely avail the writer, translator, or publisher much as a passport to support and patronage. The main difficulty of these two much-considered classes of the medical fraternity must be at present to make a choice. The task of aiding them in this we find not only difficult but invidious. We think they will not go far wrong if they provide themselves with one book compiled by an American, one by an English, and one by a German author. The present volume might represent the last mentioned. It, too, has its good points. The second and last edition of the original was published nearly ten years ago, but that is not a matter of great consequence in a book of this kind.

The Student's Manual of Histology, for the Use of Students, Practitioners, and Microscopists. By CHARLES H. STOWELL, M. D., Assistant Professor of Physiology and Histology at the University of Michigan. Detroit: George S. Davis. 1881.

It is a little difficult to assign this work its proper place. It does not pretend to be a thorough treatise on histology, and yet it is more ambitious than most of the works on technical methods, of which we have of late seen so many. It has a great many figures, most of which are from approved sources, but they are, as a rule, poorly executed. There are some discussions in the text which would suggest a larger work, as for instance, that on the origin of the red blood corpuscles. Dr. Stowell is evidently very well read on his subject, and there is a good deal that is valuable in the book. His remarks on the recognition of blood corpuscles for medico-legal purposes deserve praise for the caution which characterizes them on some points. Among these, however, we cannot class his instruction to wash and then stain corpuscles from a clot that may be too highly colored.

In the chapter on bone there is a very serious error due to confounding bone corpuscles with lacunæ. On page 84 there is a figure of two of the latter, canaliculi and all, described as the former. This is the more extraordinary that on the very next page we are told that in the living bone the lacunæ contain protoplasmic cellular matter.

In the chapter on the connective-tissue group we are surprised to find that migratory cells are described as lymph cells out of their proper places, which latter fact we think an assumption. The book has merits and defects like most others but, like many others also, it does not have a satisfactory *raison d'être*. It does not pretend to fill the place of an elaborate treatise and we have plenty of good manuals telling the student how to work.

T. D.

Medical and Surgical Journal.

THURSDAY, MAY 5, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY.

No. 4 PARK STREET, BOSTON, MASS.

INSANE HOSPITAL CONFLAGRATIONS.

It will be remembered that we called attention to this subject in our issue of March 24th. We regret to be called on so soon again to chronicle another fire. The following telegram from the *Advertiser* of April 20th gives the details in brief:—

"ANNA, ILL., April 20th. A fire broke out in the bath-room of the second floor of the north wing of the Illinois Southern Hospital for the Insane at 11.30 o'clock Monday night. After getting the patients out an effort was made to check the fire, but as the building had a mansard roof it was not until the centre of the building was reached that the fire was mastered. A patient from Monroe County, named N. Thierkle, was burned to death. The loss is \$150,000."

In the same article we spoke of the importance of trained fire corps in insane hospitals; we quote these sentences from Dr. Arthur Mitchell, Scotch Commissioner of Lunacy, as being *apropos*. Speaking of the management of the Barony Asylum, he says: "The recent burning of one of the towers scarcely affected the appearance of any part of the house, and in no way interfered with the usual daily life of the inmates. It is very creditable to the management that, even when the fire was at its height, the wants of the patients received their customary attention, and perfect tranquility was maintained. No confusion occurred in any part of the establishment, and neither patient nor attendant received any injury. *The importance of possessing a trained and regularly exercised fire brigade was made very apparent.* By their exertions the spreading of the fire was prevented."¹

THE HORACE MANN SCHOOL FOR THE DEAF.

THE going to and coming from school of a crowd of children is always an attractive sight, and wherever you see the happy crowd just loose from school close observation will generally show more than one individual of mature years who pauses in his occupation to watch and ponder over the pleasant spectacle.

No one can pass a certain corner in the city at the hour of opening or closing school without having his attention drawn to a more than ordinarily interesting group of school children with bright and mobile faces, and a superfluity of gestures, and a very few moments will suffice to show that they are deaf and dumb.

Members of the Massachusetts Medical Society who were present at a late meeting will recall the very interesting address upon Visible Speech, by A. Graham Bell, in which he explained a method of teach-

ing deaf mutes the use of spoken language. At the close of his remarks several deaf mutes were introduced, who illustrated the results attained by his method. Though the pupils were somewhat disconcerted by the presence of so large an audience, and their speech was constrained and artificial, the exhibition was a striking and impressive one. Those who listened to the declamations of those pupils will be interested in a short account of The Horace Mann School for the Deaf, which appears in the *Popular Science Monthly* for May.

The school was suggested in 1843 by Horace Mann, secretary of the Massachusetts Board of Education, but it was not until 1869 that the school was actually opened. It now numbers about eighty pupils of various ages and stages of advancement. Professor Bell's system has been used since the beginning, but attempts are being made, with apparent success, to depart somewhat from this arbitrary method.

All the teaching must be in some way objective; the beginning is made by writing words on the black-board, and associating the word with the visible object. A number of such names are thus written, repeatedly, until the pupil learns the association, and advance in writing is earlier and easier than among children who hear.

The first vocal attempt is to close the lips and make the sound of the letter *m*, which he does by feeling the curious vibrating sensation in his teacher's lips and chin and trying to imitate it.

The congenital mutes and the semi-mutes, or those who become deaf in different stages of age and development, are separated so far as possible, for the semi-mutes usually retain a few words or sentences upon which to build, while those who have never heard must begin far behind them. Of those with acquired deafness scarlet fever is considered the cause in about one third of the cases.

Pupils are received at the early age of four and five years, and instruction is carried through all the studies of the upper grammar schools. The results attained vary, of course, in accordance with the natural gifts of the pupil.

Although Massachusetts was somewhat later than some of her sister States in the establishment of public schools for the instruction of deaf-mutes, it is interesting to know that she contributed somewhat largely to the first school of the kind in the United States, that at Hartford, and the school at Northampton, we believe, has the distinction of being the first school in the United States where articulation was systematically taught. Similar institutions now exist in a large number of States.

The sensitive feelings of the children are evidently carefully regarded by the authorities. The school was first known as the Boston School for Deaf Mutes, but as the pupils learned to speak they objected not unnaturally to being longer called "mutes;" in changing the name the city not only showed a deference to its still deaf though no longer dumb wards, but erected to the man who had the humanity to suggest the establishment of the school, a monument more lasting

¹ Journal of Mental Science, April, 1881, page 100.

than brass, and also much more graceful than many of the brazen images by which it attempts to bestow immortality.

MEDICAL NOTES.

—The method of teaching anatomy from the living model, to which attention was called in our issue of April 14th, has been practiced and appreciated for some time past, as we are informed, at the Harvard Medical School.

—We have received too late for useful insertion a notice of the annual meeting of the Connecticut River Valley Medical Association, which was held at Bellows Falls Wednesday, May 4th. The president delivered an address on Death; Its Physical Aspect.

—The Board of Health of Newton, Mass., has made the sensible regulation that before any work of plumbing or drainage is undertaken in any building a complete plan of all the pipes, traps, cess-pools, and other items shall be submitted to the city engineer for his approval or modification, as the case may be, and that no work shall be carried out except in accordance with a plan so approved or modified. — *Sanitary Engineer*.

—Dr. Little, of Shanghai, has communicated a method of treating abscesses of the liver by large and direct openings with antiseptic precautions. The plan consists in determining as accurately as possible the seat of the purulent collection, and in verifying the diagnosis by means of the aspirator. Very free openings are then made with a bistoury into the abscess, the aspirator needle being used as a director.

—Many people may have noticed the often disgusting odor proceeding from the size and paste of paper-hanging pervading an apartment for some time after the paper has been newly hung. M. Vallin, in the *Revue d'Hygiène*, reports an interesting case, which has induced him to make some inquiries in this matter. A lady, who, from time to time, came to town to supervise the decoration of her house, was three times successively seized with violent sickness and headache after sleeping in a newly-papered room. M. Vallin was struck with the putrefactive odor which pervaded the atmosphere, and, after examining into the matter, came to the conclusion that it proceeded from the wall. It was found that a horrible putrefactive odor proceeded from the size-pot, with which the paper-hanger, in the next room, was continuing to hang the wall-papers, and that his size was in a state of putrefactive change. On making further inquiries, various other cases have come under his notice in which illness has palpably been produced by the use, by paper-hangers, of size and paste undergoing or speedily entering on septic change; and it is extremely desirable that this should be borne in mind, and, if necessary, a little oil of cloves, salicylic acid, or some other antiseptic agent should be added to the material which they use for this purpose, or, at any rate, care should be taken to avoid these disagreeable consequences of carelessness which is only too common. — *Sanitary Record*.

—A temporary Museum will be opened in the rooms of the Geological Society during the sittings of the International Medical Congress in London this summer. All objects of novelty or rarity having reference to the processes of disease or the results of injury will be acceptable for exhibition. The following are some subjects to which it is intended to devote special attention: (a.) Methods of preparing, mounting, and preserving specimens. (b.) Special groups of injuries and results of disease (as illustrated by drawings, photographs, models, casts, or preparations). (1.) Injuries to Bone: Fracture of carpal end of radius, recent and old; specimens proving bony union after transverse fracture of patella; rare forms of fracture, dislocation, and separation of the epiphyses; repair of skull-bones after injury, especially of basis cranii. (2.) Bone Disease: Osteitis deformans; collections of scoliotic and other pelvic deformities; specimens of necrosis without suppuration; mollities ossium; specimens of rickets in the lower animals. (3.) Results of Operations: Arteries after catgut or other ligatures; osteotomy for genu valgum; specimens showing repair after excision of joints. (4.) Joint Disease: Charcot's joint-disease; rare forms of rheumatic arthritis and gout. (5.) Skin Disease: Rodent ulcer and allied forms; mollusum contagiosum. (6.) Parasitic and other diseases which occur solely or especially in particular countries; Madura foot, anthrax, etc. (7.) Lymphadenoma. (8.) External hydrocephalus. (9.) Rare and important specimens of comparative pathology. (c.) Arrangements will be made for the exhibition in groups on special days (of which due notice will be given) of Living Examples of certain Rare Diseases, etc. The following are the subjects selected by the Committee for illustration, in this manner: (1.) Addison's disease (bronzed skin and disease of supra-renal). (2.) The coincidence of true gout and rheumatic arthritis. (3.) Charcot's joint-disease. (4.) Myxoedema. (5.) Syphilitic bone-disease in children, simulating scrofula and rickets. (6.) Mollities ossium. (7.) Primary muscular atrophy. (8.) Rupture of brachial plexus or other large nerve-trunks. (9.) Scleroderma or morphea. (10.) Keloid of Alibert, especially with reference to its spontaneous disappearance. (11.) True leprosy. (12.) Lupus erythematosus. (13.) Xanthelasma. All communications regarding this Section should be addressed to the Secretary, 16 Palace-road, St. Thomas's Hospital, London, S. E.

—The empress of Germany, who, as is well known, is interested in all projects for the alleviation of the sufferings of the sick and wounded, has expressed her lively interest in the coming International Medical Congress, and her intention to delegate the distinguished director of the Augusta Hospital in Berlin (her special charge), Professor Küster, to represent her at the Congress.

MEDICO-LEGAL.

—*Winspear v. Accident Insurance Co.* (Court of Appeal. November 29, 1880.) By a policy of insurance, defendants agreed to pay to the representa-

tives of W. one thousand pounds if "the insured shall sustain any personal injury caused by accidental, external, and visible means, . . . and the direct effect of such injury shall occasion the death of the insured." The policy provided "that the insured shall not be entitled to make any claim under this policy for any injury by any accident unless such injury shall be caused by some outward and visible means, of which proof satisfactory to the directors can be furnished; and that this insurance shall not extend . . . to any injury caused by or arising from natural disease, or weakness, or exhaustion, consequent upon disease, . . . or to any death arising from disease, although such death may have been accelerated by accident." The insured, whilst crossing a stream was seized with an epileptic fit, fell, and was drowned. He did not sustain any personal injury to occasion death other than drowning. The plaintiff recovered judgment, and defendants appealed.

Cohen, Q. C., and Gainsford Bruce, for defendants. Assuming that drowning is an injury caused by accidental, external, and visible means, the case is nevertheless not within the policy, for what really occasioned the death was the epileptic fit, which caused the assured to fall down in the water and be drowned. The defendants are protected by the proviso, for this was a death arising from disease. [Brett, L. J. If there was an injury caused by accident, which accident was caused by natural disease, where is the exception applying to that?]

Lord Coleridge, C. J. I am of opinion that this judgment ought to be affirmed, and on the following plain and short grounds: The circumstances of the death are set out in paragraph four of the special case, which is a perfectly clear statement that the deceased died from drowning in the brook. Now drowning has been decided to be an injury "caused by some outward and visible means." I am therefore of opinion that the injury by which the assured died comes within the risks which the defendants have undertaken. Then the only question is whether the case comes within the proviso contained in the policy so as to exempt the defendants from liability. That clause provides that no claim shall be made for any injury from accident, "unless such injury shall be caused by some outward and visible means," etc. The remarks I have already made apply to these words, and therefore the case is clearly not within the first part of the proviso. Then it goes on to provide that the "insurance shall not extend . . . to any injury caused by or arising from natural disease, or weakness, or exhaustion, consequent upon disease, . . . or to any death arising from disease, although such death may have been accelerated by accident." Here the injury was caused by an accident, that is, drowning, and therefore I think that this clause has no application. It seems to me that the words of the policy must mean what they say, and in such a case as this the injury is what really causes death. Therefore, the defendants are clearly liable, and the judgment of the court below must be affirmed. Baggallay and Brett, L. JJ., concurred. — *Reporter*.

Miscellany.

LONDON LETTER: FROM OUR LONDON CORRESPONDENT.

COLOR-BLINDNESS.

MR. EDITOR, — Last night the Ophthalmological Society of the United Kingdom held a special meeting to receive the first report of its sub-committee for the investigation of color-blindness.

This report dealt with the results afforded by the examination of some 18,088 individuals. The average percentage with defective color perception had been amongst males 1.75, amongst females 0.1 per cent., or the defect was rather more than ten times as rare in females as in males. The examination had extended to Ireland, where amongst 2859 male children examined 4.2 per cent had been detected with defective color perception.

In the Merchant Taylor's School in the metropolis three pairs of color-blind brothers existed amongst 500 pupils. The prevalence of defective color perception had appeared to diminish as those examined had risen in the social scale.

Thus the police yielded 3.7, middle-class persons 3.5, professional persons 2.5, Eton boys 2.46 per cent. of more or less color-blind.

Persons of Jewish extraction, members of the Society of Friends, and deaf-mutes were grouped as exceptional classes. Their existence as such in relation to the prevalence of color-blindness has come out conspicuously, as may be gathered from the following: Amongst females of Jewish extraction no less than 3.1 per cent. were found with defective color perception; in the Society of Friends 5.5 per cent. of the females, and 2.4 per cent. of the female deaf-mutes were similarly conspicuous: whilst what was described as pronounced color-blindness, extreme examples of the defect, were found amongst the males of the three above named classes to the percentage of 4.9, 5.9, and 13.7, respectively.

The examples of the peculiarity were so prevalent as to reach close upon fifteen per cent. in one large college belonging to the Society of Friends, who had been most obliging in facilitating these investigations, and to whom it will be remembered Dalton, the distinguished describer of the defect, belonged. To this fact was due much of the comicality attaching to the well-known tale of Dalton having worn in the public streets his scarlet university gown, which he judged to be of saue color as the hedge rows, and not of a prohibited tint.

The sub-committee had not detected any case of monocular defective color perception, but as Mr. Carter suggested such would of necessity escape recognition unless each eye were tested separately. Mindful of Professor Holmgren's case, in which there was color-blindness well-marked in one, and but slightly indicated in the fellow eye, Mr. Carter suggested that a re-examination of the individual eyes of those who had been passed as slightly defective in color perception was likely to furnish more to the class of which Holmgren's patient was a type; as, if the causation of the defect lay in the retina (which appeared likely), its unilateral occurrence should not be excessively rare.

Mr. Frost mentioned a color-blind draper who required to have many of his wares ticketed as to the

color, who begat seven sons and three daughters, of whom six sons were extreme examples of color-blindness, whilst the remaining children had normal color perception; notwithstanding which, however, one of the daughters had a son, who, at the age of twenty-one, was too red blind to distinguish between emeralds and rubies, though a jeweler.

Mr. McHardy mentioned having noticed color-blindness as being most unduly prevalent amongst successful wood-engravers, a circumstance for which Mr. Carter suggested the explanation that possibly that trade was much confined to families in which it descended, like color-blindness, from generation to generation; whilst the president, Mr. Bowman, thought it likely that color-blind persons with artistic taste and ability had a tendency to become eliminated from working in colors and to drift, by a process of natural selection, into work in black and white.

Reference was made by Dr. McHardy to the experts' report upon the color perception of the Connecticut railway employes, and to the important direct testimony of the fatal consequences of employing color-blind navigators, which has been furnished by the collision in Norfolk harbor.

The president alluded to the urgent need of imperial and international legislation in reference to color-blindness and visual acuteness, also to the great and disinterested service ophthalmologists, by lending themselves to these investigations, were rendering to the traveling community, whose safety could not be secured until the color-blind had been eliminated, as could only be done by expert examiners, from those who were called upon to distinguish between colored signals.

Dr. Brailey, who read the committee's report, favored three factors as participating in connection with the existence of defective color perception: (1.) A physical defect probably situated in the eye itself. (2.) Education. (3.) Intermixture.

The first rapidly lent itself in connection with the known transmissibility of the defect. The second, if operative, must operate at an exceedingly early period in the infantile life, and thus possibly explained the rarity of defective color perception in girls who, being notorious for precocity, it was fair to assume developed their faculty of observation earlier than boys. The third was strongly supported by the facts elicited in connection with persons of Jewish or Quaker extraction. The former had for numberless generations intermarried, partly through necessity and perhaps in some cases through choice; whilst the latter, altogether a small and tolerable modern community, had until recently been prevented by the rules of the Society of Friends from marrying out of the sect. Dr. Bradley questioned the correctness of regarding red and green blindness as distinct. He considered the former an exaggerated degree of the latter, and had found there were vast numbers of cases intermediate between the two, which in many well-marked instances it was perfectly easy to recognize as standing at either end of a scale.

NEVOID EUPHANTHASIS.

At the Clinical Society to-night, Mr. Thomas Smith showed a living specimen, the third he had seen of this affection, which he has described in an illustrated paper, in the fifth volume of the St. Bartholomew's Hospital Reports. The patient, a lad aged fourteen, had exhibited superficial nevoid changes over his entire

right half since birth. The right leg, which was covered with an exaggerated growth of hair, appeared to be three times as bulky as its fellow. In Mr. T. Smith's first case, which was somewhat similar, the portions of the limb when squeezed gave the same sensation that a wet sponge would under like circumstances. As a preliminary measure, he had directed that limb to be carefully bandaged, with the sequence that the patient became excessively ill and died; as Mr. T. Smith now believed in consequence of the bandaging. In his first case the external iliac vein was of normal size, whilst the internal was not smaller than a man's thumb, and the navoid tissue, which contained considerable sinuses, extended into the pelvis. His second case occurred in a patient whose position enabled her to command every luxury that money could procure, she had attained the age of twenty-one years and appeared likely to live, with the aid of a weak elastic stocking, through the restricted career which her condition left open. The patient before the society had had the limb gently bandaged for a brief period, during which her health had so materially suffered as to recall the experience afforded by the first case, and lead to an immediate abandonment of a form of treatment which could so easily prove mischievous by forcing a vast volume of blood into a restricted area of the circulatory system.

MENINGOCELE AND MATERNAL INFLUENCES.

A hideous example of this deformity was quoted wherein much of the brain might be said to occupy the nose, and the infant had lived between three and four months. The mother attributed the malformation to a shock she experienced while three months pregnant with him, when in identifying a relative's body, subsequently to the autopsy, her hand came unexpectedly on to the irregularity of the deceased's forehead, which had been occasioned by removal of the skull cap.

LONDON, April 9, 1881.

LETTER FROM JAPAN.

A JAPANESE PHARMACOPEIA.

MR. EDITOR.—The question uppermost in the minds of men in the financial circles of this Island Empire is that of the decline of the paper currency as compared with that of the metallic; in the diplomatic, that of the revision of the commercial treaties; in the world of trade, that of the "balance of trade"; in the religious world, that of the advance of Sintoism in Okinawa, of the Greek doctrines about Tokio, and of Protestantism at Etchizenbori, and of the completion of Hongandji, a famous temple, near the foreign concession at Tokio; and in the medical world, that of a pharmacopœia.

At present there is no uniformity. In one hospital the English pharmacopœia, in another the American, in a third the Dutch, and thus on through the list, according to the nationality of the foreign physician employed in the same. Thus about these hospitals as centres have grouped practitioners using a different standard for preparations from that in use in the next hospital town. Also the druggists, slowly working out the mysteries of the Chinese drug-list, would enter into this confusion of authorities, flounder about, and, in all probability, would get up a system of their own. The confusion in matters of pharmacy in Japan is now greater than that which reigned in the United States

when the Dublin, the Edinburgh, the London, and the Codex were found on the shelves of every reputable drug shop. Small parts only of either of the Western standards have been translated into Japanese. No one book, complete in itself, has been translated or compiled for the use of the apothecary and the physician. The government some years since issued regulations for the examination of candidates for license to engage in the business of apothecaries; specified those who should be exempt from such examinations; called upon "the local authorities to take proper measures to distinguish such as have passed a satisfactory examination," and directed that any person who shall henceforth become an apothecary shall be examined in, among other subjects, "the general principles of pharmacy and the general principles of formulary."

The Imperial government decided at the close of Meiji 13 (1880) to have a standard pharmacopœia compiled and published. A special commission has been appointed by H. E. Mitoyoshi Matsukata, the Minister of the Interior, for this purpose. It is composed of the following gentlemen:—

Hosokawa, member of Gheuro-in, President.
Miyake, Professor of Medical University, Tokio.
Matsumoto, Surgeon General of Army.
Totsuka, Surgeon General of Navy.
Hayashi, Surgeon I. J. Army.
Nagayo, Director Department of Hygiene.
Ikeda, Imperial Surgeon.
Nagamatsu, Pharmacist, Army Department.
Takagi, Medical Staff.
Shibata, Sanitary Department.

Ten Japanese, and the following Europeans now in government service:—

Dr. Beukema (Holland) Ken Hospital, Kanagawa.
Dr. Baelz, Professor Tokio University, German.
Dr. Louggard, Professor Tokio University, German.
Dr. Geerts, Professor Tokio University, German.
Dr. Eykman, Professor Tokio University, German.

The work of the commission was entered upon at the first meeting, which was held at Tokio on January 11th. It is to be hoped that this commission will make diligent progress, will select all that is of superior quality in each of the pharmacopœias, and will incorporate such selections, with proper emendations, into a volume whose characteristics shall be plainness, simplicity, permanency, and brevity. And that, later, it shall be faithfully and conscientiously rendered into progressive Japanese, by appropriate and accurate equivalents.

Of the Japanese portion of this commission, the working, progressive part is from the army medical department, Matsumoto, Totsuka, and Ikeda were of the early students who flocked to Nagasaki to learn of the Dutch teachers. These are the men who have been in the van of medical progress in Japan, the men who have urged the claims of the new learning upon the attention of the government, the men who have battled nobly against the prejudices and interests of a medical school established for centuries, the men who have demonstrated, in so far as their personal influence lay, the value of Western medicine. They have gained the day in official circles, in the army, navy, and civil service hospitals, but the masses of the practitioners and of the people are not in accord with the innovations. There are at present in Japan, according to the *Mi-Nichi Chim-bun*, 65,200 practitioners of medicine, of which only 504 hold diplomas such as the notification of 1876 calls for. Of this large number of "doctors" it

is estimated that sixty-six per cent. follow the Chinese school, twenty-one per cent. the "western system" (that is, having a meagre knowledge of a few drugs and their applications), and thirteen per cent. follow the mixed Chinese and Japanese schools of practice.

As may be known to many of your readers, the Japanese government has been making certain financial experiments on an extended scale, such as floating upwards of 160,000,000 yen of fiat paper, and establishing a large number of national banks based on the national bonds; it has been engaging in commercial and industrial operations usually left to private enterprise; and has been making very extensive purchases of material for the army, navy, and civil services, all of which must be paid for in coin. The result is that specie has been drawn out of the country or locked up; that the bonds are quoted at about 68 with a par of 100, that the fiat paper ranges from 170 to 180 as compared with the silver yen; that the prices of commodities have enhanced much faster than salaries and prices of labor, with resulting inconveniences and even suffering. There is a general feeling, which the government takes no measure to disabuse, that all the embarrassments are owing to the excess of imports over exports, that the trade with foreigners is disadvantageous and prejudicial to the interest of Japan, and that the people and the government should draw once again a cordon of obstruction about the Empire. A man by the name of Sada, reports the *Choya Chim-bun*, has proposed publicly that the people of Japan shall use no articles which have been imported from America or Europe. This idea has obtained considerable support. Many so-called societies have been formed in Kioto and Osaka with this object. A doctor of the Chinese school is now occupied in the organization of a similar society for similar ends in medicine.

MEDICAL ORGANIZATION OF THE ARMY.

A recent estimate of the population of Japan has placed the figures at 33,300,675. The Japanese army, on its present peace footing, is 39,891 men. In a few years it is expected to embrace 160,000 men, in the following order: An active army, a reserve of the active army; a territorial army, and a reserve of the territorial army, each with a peace footing of 40,000 men. The medical department is in charge of two Inspector Generals of Health, with the rank of general of brigade. This service is independent of the war ministry. It is divided into four sections:—

Section I. General staff.

Section II. General Hospital, Tokio.

Section III. Hospitals of Teindai, that is, the six military divisions of the Empire.

Section IV. Regimental Service.

In Japan, the infantry alone is organized by regiments. Each regiment has one surgeon of the second rank. The artillery and cavalry service are dependent on the post surgeon for their medical attendance. The veterinary corps of officers is at present under the control of the army medical department. The veterinarian highest in rank has a position corresponding to chief of battalion. The pay of the regimental surgeon is fifty yen per month, and that of the assistant, when one is assigned, only thirty yen (one yen silver is now equal to ninety-one cents American gold). As all departments in Japan receive their pay in *Satsu*, or government notes, and as this paper is now only worth fifty-seven sen silver coin per yen, it is evident that the

medical service is very poorly paid. As a matter of fact, with the exceptions of the general staff, the talent and education in the army medical department is inferior to that in the civil service.

TITLES, DUTIES, SALARIES, AND RANKS IN THE MEDICAL DEPARTMENT OF THE JAPANESE ARMY, 14 MEIJI (1881.)

Japanese Title.	Duties.	Salary.	Rank.
Gun-I Sō-Kwau	Inspector General.	Yen. 3000	General of Brigade.
Gun-I-Kwau.	Chief Med. Dept.	2540	Colonel.
Yaku-Sai-Kwau.	Chief Med. Purveyor.	2540	Colonel.
Gun-I-Sei, I.	Staff Surgeon.	1740	Lieut.-Colonel.
Yaku-Sai-Sei, I.	Staff Purveyor.	1740	Lieut.-Colonel.
Gun-I-Sei, II.	Staff Surgeon, 2d rank.	1140	Major.
Yaku-Sai-Sei, II.	Staff Purveyor, 2d rank.	1140	Major.
Bu-I-Kwau.	Chief Veter. Dept.	1044	Chief of Battalion.
Gun I.	Regimental Surgeon.	750	1st Lieut. of Infantry.
Sai Kwau.	Regimental Purveyor.	750	1st Lieut. of Infantry.
Bu-I, I.	Veterinarian, 1st rank.	624	1st Lieut. of Infantry.
Bu-I, II.	Veterinarian, 2d rank.	578	1st Lieut. of Infantry.
Gun-I-Fuku.	Passed Asst. Surgeon.	510	2d Lieut. of Infantry.
Sai-Kwau-Fuku.	Passed Asst. Purveyor.	510	2d Lieut. of Infantry.
Bu-I-Fuku, I.	Passed Asst. Vet., 1st rank.	384	2d Lieut. of Infantry.
Bu-I-Fuku, II.	Passed Asst. Vet., 2d rank.	336	2d Lieut. of Infantry.
Gun-I-Ho.	Apothecary.	420	3d Lieut. of Infantry.
Sai-Kwau Ho.	Apoth. Dept. of Stores.	420	3d Lieut. of Infantry.
Bu-I-Ho.	Farrier.	254	3d Lieut. of Infantry.

KAITAKESHI HOSPITAL, SAPPORO, JAPAN, February, 1881.

CORRECTION OF THE RHODE ISLAND MEDICAL SOCIETY'S REPORT.

MR. EDITOR.—In your issue of April 11, 1881, under the heading of the Rhode Island Medical Society, the reporter was led into some inaccuracies, which I beg leave to correct.

The case of ununited fracture that I reported was of the *tibia*, and not of the femur, and the limb was not "encased in plaster for five months," but in my care for that time. It was originally put up in plaster.

Then, as to the case of litholapaxy, I merely stated that fearing a hard stone I used a Thompson fenestrated lithotrite instead of a delicate instrument I had used for measurement. I found the stone measured one half inch in its longest diameter and nearly one quarter inch in thickness.

I may take this opportunity of recording another case of litholapaxy in a man aged forty-three. The stone was small and hard, and proved to be entirely oxalate of lime. I used the Thompson fenestrated lithotrite, and removed forty-three grains. The length of the operation was about thirty minutes. A month after the operation no trace of any fragment was to be found, and the patient had been entirely free from all symptoms. He was up on the third day, and out of doors in a week. Very truly yours,

EDWARD T. CASWELL.

PROVIDENCE, April 25, 1881

A SOLUTION OF MORPHIA.

MR. EDITOR.—If "Querist" will refer to the *Philadelphia Medical Times* of January 1, 1881, he will find an interesting article, by Dr. H. A. Wilson, on Soluble Compressed Pellets. Those of us who are suspicious of a long-kept solution of an organic salt like morphia, and who are disinclined to inject that article mixed with, or perhaps changed into, a fungoid growth, like penicillium, — and there are some who would hesitate to use even small amounts of carbolic

or salicylic acids or other preservatives, — have been in the habit of carrying their morphia for subcutaneous use in the shape of powders. I have received from Messrs. Wyeth Brothers, of Philadelphia, within a few days, some of their pellets, made after the suggestions of Dr. Wilson, with the coöperation of Professor Roberts Bartholow and Professor Wolff, which are much more satisfactory, to my mind, than the powders I have used for many years. This firm prepares at least eighteen varieties of salts of morphia, atropia, and strychnia in definite amounts, and in perfectly soluble form. They are joined with sulphate of soda, a salt which is in no wise incompatible with the organic salts, and causes no pain or irritation, but even assists absorption. Moreover, morphia compressed alone becomes hard and insoluble after a time, but the chloride or sulphate of soda intimately mixed with the morphia acts as a disintegrator, and by its ready solution leaves it in a state of fine subdivision ready to be acted on by water. Dr. Wilson briefly summarizes the advantages of these pellets in four propositions: They are of convenient size, they may be used by the mouth if desirable, they are in fixed and definite doses, they are certainly and rapidly soluble. I shall be glad to show the new pellets to "Querist" or any other professional brother.

F. H. B.

AN APE-HEADED NATION.

At a meeting of the Anthropological Institute, held on March 22d, Professor Flower exhibited a collection of crania from the island of Mallicollo, in the New Hebrides, which had been lately presented to the Museum of the Royal College of Surgeons by Mr. Luther Holden. The peculiar conformation of the heads of the people of this island attracted the attention of Captain Cook and the naturalist Foster, who accompanied the great navigator on his second voyage, and who writes that "the depressed and backward inclining forehead causes an appearance in the looks and countenances of the natives similar to those of monkeys." Yet Cook bears testimony to the activity, intelligence, and honesty of this "ape-like nation," as he calls them. A few years ago, Mr. Busk described some skulls collected in the island by the late Commodore Goodenough, and found that they all showed signs of having undergone alterations in form, from pressure applied in infancy. The present collection corroborates Mr. Busk's views; some of the skulls being deformed to a remarkable degree, and closely resembling the well-known ancient Peruvian crania from the neighborhood of Lake Titicaca. This is the more remarkable, as on no other of the numerous islands in the neighboring ocean is this practice known to exist. Besides the deformed crania, the collection contained several monumental heads, said to be those of chiefs. In these the features are modeled in clay upon the skull, apparently with the intention of preserving a likeness of the dead person. The face is painted over with red ochre, artificial eyes are introduced, and the hair is elaborately dressed and ornamented with feathers. In one case the hair has been entirely removed and a neatly made wig substituted. The head thus prepared is stuck upon a rudely made figure of split bamboo and clay, and set up in the village temple, with the weapons and small personal effects of the deceased. This is a custom not hitherto known to exist among the Mallicollese, and its motive is not completely understood; but it is obviously analo-

gous to many others which have prevailed throughout all historical times and in many nations, manifesting itself, among other forms, in the mummified bodies of the

ancient Egyptians, and the marble busts over the mouldering bones in Westminster Abbey. — *British Medical Journal*.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 23, 1881.

Deaths reported 3043 (no return from Buffalo); 1102 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 679, consumption 457, lung diseases 416, diphtheria and croup 193, scarlet fever 121, cerebro-spinal meningitis 75, typhoid fever 59, small-pox 54, measles 39, malarial fevers 39, diarrheal diseases 37, whooping-cough 19, erysipelas 18, typhus fever 13, puerperal fever 11, malignant pustule one. From *typhoid fever*, Philadelphia 19, New York 11, Pittsburgh 10, Chicago four, Brooklyn and Providence three, Cincinnati two, Boston, New Orleans, District of Columbia, Lowell, Salem, Quincy, and Westborough one. From *small-pox*, Philadelphia 33, Chicago 11, New York nine, Cincinnati one. From *measles*, Cincinnati 10, New York nine, Boston and St. Louis three, Philadelphia, Brooklyn, Chicago, Worcester, and Malden two, Baltimore, New Orleans, Providence and Nashville one. From *malarial fevers*, New York 14, New Orleans nine, St. Louis seven, Chicago three, Brooklyn two, Philadelphia, Baltimore, District of Columbia, and New Haven one. From *diarrheal diseases*, New York 12, District of Columbia five, Philadelphia, Brooklyn, and Baltimore three, Chicago, St. Louis, New Orleans, and Nashville two, Cincinnati, Milwaukee, and Providence one. From *whooping-cough*, Chicago four, New York, Philadelphia, and New Bedford three, Cincinnati two, Baltimore, New Orleans, Providence, and Salem one. From *erysipelas*, New York six, Philadelphia five, Brooklyn, St. Louis, Baltimore, New Orleans, Worcester, Chelsea, and Brookline one. From *typhus fever*, New York 13. From *puerperal fever*, St. Louis five, Brooklyn, Cincinnati, Milwaukee, Providence, Worcester, and Holyoke one. From *malignant pustule*, Newburyport one.

The mortality from cerebro-spinal meningitis has decreased from 80 for the week ending April 16th to 75.

Ten cases of small-pox were reported in Brooklyn, 31 in Chicago, one in Boston, one in Cincinnati, one in New Orleans, four in Pittsburgh, one in New Haven; diphtheria 37, scarlet fever 12, typhus fever seven in Boston; scarlet fever 20, diphtheria nine in Milwaukee; measles 45, röteln 14, scarlet fever 14, diphtheria seven, typhoid fever two, erysipelas one in Providence.

In 44 cities and towns of Massachusetts, with a population of 1,123,141 (population of the State 1,783,086), the total death-rate for the week was 21.26, against 21.43 and 24.16 for the previous two weeks.

For the week ending April 24, in 149 German cities and towns, with an estimated population of 7,909,880, the death-rate was 26.7. Deaths reported 4061; under five 1888; pulmonary consumption 640, acute diseases of the respiratory organs 425, diarrheal diseases 144, diphtheria and croup 140, scarlet fever 77, whooping-cough 55, typhoid fever 53, measles and röteln 26, puerperal fever 15, typhus fever (Königsberg five, Danzig and Erfurt two, Thorn, Posen, Leipzig, and Frankfurt-a-O. one) 13, small-pox (Königsberg four, Berlin two, Munich, Frankfurt-a-O., Aix-la-Chapelle, and Essen one) 10. The death-rates ranged from 11.7 in Weisbaden to 39.2 in Essen; Königsberg 34.7; Breslau 33.5; Munich 36.9; Dresden 28.8; Berlin 25.3; Leipzig 21.3; Hamburg 21.9; Hanover 16.6; Bremen 26.4; Cologne 27.3; Frankfurt 24.3; Strasburg 36.8.

For the week ending April 9th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 22.4. Deaths reported 3264: acute diseases of the respiratory organs

(London) 359, measles 78, small-pox (London 72) 73, whooping-cough 71, diarrhoea 30, fever 26, diphtheria 16. The death-rates ranged from 16.0 in Portsmouth to 28.0 in Liverpool; Manchester 26.1; Sheffield 23.7; Birmingham 24.5; Leeds 21.8; London 21.6; Bristol 19.0. In Edinburgh 22.1; Glasgow 24.5; Dublin 38.0.

In the 21 chief towns in Switzerland, for the week ending April

9th, population 479,934, there were 37 deaths from acute diseases of the respiratory organs, diphtheria and croup 16, diarrhoeal diseases 14, typhoid fever eight, measles three, small-pox three, scarlet fever two. The death-rate of Geneva was 18.7, Zurich 10.4, Basle 25.1, Berne 36.3, St. Imier 58.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 23, 1881, TO APRIL 29, 1881.

BACHE, D., major and surgeon. Granted leave of absence for one month on surgeon's certificate of disability, to take effect as soon as a medical officer reports for duty at Benicia Arsenal and Barracks. S. O. 62, Division of the Pacific, Department of California, April 16, 1881.

GREENLEAF, CHARLES R., major and surgeon. To report to superintendent-general recruiting service to conduct a detachment of recruits to Department of Dakota, and on completion of this duty to join his station (Fort Shaw, Montana Territory). S. O. 95, A. G. O., April 26, 1881.

CROCKFORD, H. M., captain and assistant surgeon. To proceed from Camp Sheridan to Fort McKinney, Wyo., and report for duty at that post. Camp Sheridan to be discontinued May 1, 1881. G. O. S., Department of the Platte, April 20, 1881.

BIARR, V., first lieutenant and assistant surgeon. So much of paragraph 1, S. O. 205, September 24, 1880, from A. G. O., as relates to him is revoked. S. O. 94, A. G. O., April 25, 1881.

CLINICAL LECTURE ON SUBPERITONEAL UTERINE FIBROIDS.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

BY PROF. T. GAILLARD THOMAS, M. D.

GENTLEMEN,—The patient who will now engage our attention, and who has been sent to us through the kindness of my friend, Dr. P. Brynberg Porter, is a native of Ireland, forty years of age, and unmarried. She states that she has been suffering for seven years, but has been able to work all the time. When asked the nature of her complaint, she replies, "I am all pains," and when requested to designate the special seat of the pain, she says that it comes "all around the lower part of the stomach and down the legs." She furthermore says that her "stomach often swells up," and that she sometimes has headache. She is regular in her monthly periods, but says that she suffers very much at such times, the pain coming on almost a week before the flow makes its appearance. When it is added that she suffers sometimes from backache, and occasionally has a slight leucorrhœa, you have the complete history of the case as elicited from the patient herself.

You will notice that there are really very few important symptoms indeed. There is a good deal of pelvic pain, certainly, and some dysmenorrhœa, but that is about all. She has, however, a certain uterine disorder in an unusually marked form. Under the circumstances, I think it has been the greatest blessing in the world to her that she has been obliged to work for her living; for if she had been a wealthy lady, with nothing to think about except her own ailments, I can hardly doubt that she would have altogether succumbed before this.

Now let me describe to you and roughly indicate on the black-board the condition of affairs that I discovered on making an examination in this case. When I carried my finger up into the vagina I found a nulliparous uterus, rather low down in the pelvis, and with a round, hard growth on its anterior surface. On resorting to conjugal manipulation, which could be employed with remarkable facility in this case, on account of the laxity of the abdominal walls, I discovered another hard mass, as large as a small cocoa-nut, situated behind the uterus, while beneath it could be felt two other similar growths. Neither of the ovaries could be detected, and the fact that all these growths moved with the uterus when it was rocked from side to side, or forward and backward, by means of the sound, showed that they were without doubt all outgrowths of that organ. The uterus is, then, the centre of at least four solid tumors, and the question now arises, What are they? There can be but one answer to this, and that is that they are uterine fibroids, although very different in character from the fibroids we frequently meet with. They can, indeed, be nothing else. If they were phlegmons they would be fixed immovably in the pelvis. They cannot be ovarian tumors, on account of their position, to say nothing of their characteristics; and if they were malignant in character other symptoms would be present, and the patient's general health would be completely broken down. Indeed, it would have been a miracle if the patient were alive at

all at the end of seven years. Finally, not to go into the process of exclusion more at length, it is impossible that they should be fecal accumulations.

I wish to call your attention particularly to the insignificance of the symptoms here, where there is such a very marked abnormal condition in the pelvis, for the reason that I know of no cases which are so apt to entice the young practitioner into giving an erroneous opinion, especially as regards prognosis, as those like the one now before us. When he finds, on making a physical exploration, such a state of affairs as we have seen to exist here, he thinks that he has made a diagnosis of the utmost importance, and, led on by his imagination to suppose that the worst results must inevitably ensue, he makes a dreadful prognosis. Every word that he tells the patient, however, is contradicted by the subsequent history of the case, and ten years afterward it may be that he will have it thrown in his teeth that he made this great blunder in regard to it. The inexperienced gynecologist can hardly realize that such a state of affairs can exist in the pelvis without producing the most serious consequences, and, therefore, I want to forewarn you especially on this point.

Klaub, in his work on the Pathology of the Sexual Organs, the deductions in which are founded entirely on autopsies and microscopical examinations, has shown that fibroids of larger or smaller size (many of them, of course, quite minute) exist in nearly forty per cent. of all Anglo-Saxon women who have reached the age of forty. The remarkable prevalence of fibroids among negro women is notorious, and in my experience it is quite exceptional to find one of them in whom one or more fibroids cannot be detected. Some years ago I had the opportunity of being present at the autopsy of a negress who died of inflammation of the lungs, and it is an actual fact that no less than thirty-five fibroids, of all sizes, were found on her person. The largest was about the size of my head, and the next as large as a cocoa nut. Thousands of women who are affected with fibroids are in happy ignorance that they have a tumor, and in this connection I would offer the following piece of advice to you: When in any case you have made the diagnosis of fibroids, do not inform the patient of the fact unless you are forced to do so; because the very name of tumor is a kind of shibboleth to most women, and it will probably have a very bad moral effect upon her. This should be observed as a general rule, although cases occasionally occur in which it is best to make the diagnosis known. It may be objected to the rule that there are some instances in which if we tell the patient that there is nothing serious the matter the future course of the case will not be in accordance with our predictions; but these are very rare exceptions indeed, and it is always possible for us to exonerate ourselves from blame by stating that the case is an exceptional one.

It is an important point in connection with the present case that the patient is approaching the menopause, after which she is scarcely likely to have any trouble whatever. As far as I am able to make out, there is every prospect of her living to a good old age, and if, when she had died at the age of ninety, for instance, an autopsy should be made, nothing abnormal would be detected about the pelvic organs except a considerable number of cretaceous particles embedded in some hard, fibrous masses of comparatively small size, the remains of the extensive growths which now surround the uterus.

But it may be asked, Is there nothing that we ought to do for this woman? Unquestionably there is something that can be done for her. The very fact of the existence of these fibroids shows that the patient's system is below par, to borrow a commercial expression. There are exceedingly few persons, as you know, who can be said to be in perfect health, and in this instance the presence of the fibroids is the evidence that something is wrong. I would, therefore, recommend a sufficient amount of exercise, a nutritious diet, and careful attention to all the emunctories of the body. I would surround the patient with the best hygienic conditions possible in her case, and, in short, would endeavor to get her system in the same condition that I would that of an individual in the first stage of pulmonary tuberculosis. She is not losing too much blood at her menstrual periods, and some efficient tonic is all the medication that she seems at present to require. It should be the physician's endeavor to cheer the patient up as much as possible in such a case as this. Such women, when they find that they have fibroid tumors are very apt to imagine the most terrible evils, and you will find that they are always asking if there is any danger of a tendency to cancer in their case. In regard to this point I may say that I never heard of but one instance of fibroid in which carcinoma occurred, and that was not very well authenticated. It is a remarkable fact that negro women never have cancer of the uterus, and yet, as I have mentioned, they almost invariably have uterine fibroids. Some time ago there was a discussion in the journals on the subject of uterine cancer in the negroes, and a distinguished medical professor of Charleston, S. C., a gentleman of immense experience in diseases of women of the African race, then stated that he had never seen a single instance of it. As another point of interest here I may mention that although I have had the opportunity of examining a vast number of cases of ovarian cyst, I have never yet met with a single instance of it in the negroes.

Original Articles.

ULCERATIVE ENDOCARDITIS.

BY G. M. GARLAND, M. D.

THE following case is interesting on account of the great obscurity which usually surrounds ulcerative endocarditis and the consequent difficulties in the diagnosis of the same.

The patient was a very fleshy man, thirty-four years old, of sedentary habits, a liberal drinker. He never had a rheumatic fever, but a mitral regurgitant murmur has been audible over his heart for ten years. Four years ago he suffered from some spinal irritation, which lasted a few months and then disappeared. Two years ago he became jaundiced, but was comparatively well after that until February 13, 1880, when he was seized with sciatica in his left leg. He says he played a game of billiards in a warm room on the previous evening, and then stood talking on the corner of the street for some time. On February 14th he was helpless in bed, but soon improved so as to sit up and move about the room, and I made my last visit on March 1st. On the afternoon of March 4th I happened to run in for a friendly call, when I found my patient in a rocking-chair, reading, but looking terribly pale and weak.

He complained of no pain, but said he was very weak, and had no appetite. His pulse was 120, rapid and feeble. The temperature was 101.5° F. I could find nothing unusual in his lungs or heart, and the sciatica was no worse, so that I was at a loss to account for his condition. On March 5th I called my friend Dr. M. L. Chamberlain in consultation. We found the patient in bed, with his face slightly cyanotic, and the breathing somewhat accelerated. His wife said he had breathed rapidly for two days. He made no complaint, except of weakness. The pain in the leg was not troublesome, and with most careful examination we could find no evidence of hip-disease, and no tenderness along the spine. The pulse was 120, feeble. Temperature 101° F. Respirations 30. No pain in chest. Percussion and auscultation of the lungs normal. Mitral regurgitant murmur and hypertrophy of heart as before. Liver and spleen were enlarged. No ascites. No oedema of legs. Finding no indications but the great weakness, we ordered gin and infusion of digitalis, and requested a specimen of his urine for examination. The urine was normal. No albumen or casts.

On March 6th he was a trifle stronger, but on the following day he began to fail rapidly. Ceased to read and grew drowsy. He began to dream a great deal, and was wandering when awake. Pain in the leg was almost gone, and he could move freely in bed.

On the 8th and 9th he began to have hallucinations and delusions, which were extremely pleasant in character. Also began to be aphasic, and swore roundly when misunderstood. He became slightly cross-eyed, and the eyes had a marked lateral vibratory movement. He failed to recognize me once, and then immediately apologized for it. The temperature and pulse remained the same as on previous visit.

March 11th. Brain trouble evidently increasing, but no paralysis of motion or sensation. Fails to recognize old friends, and is rambling all the time. Hypostatic congestion of lower lobe of right lung. The face is more or less cyanotic and cold to the touch, although the internal temperature is 101.5° F. Heart is working harder, as shown by heaving of chest, but no other change in that organ could be detected. Pulse 120.

March 12th. Patient has been unconscious for twelve hours. Moves freely in bed, however. Vomits all food and medicine. Speech is thick. Both sides of chest full of loud, coarse, mucous râles. No oedema of extremities. In trying to feel of feet to see if they were cold, my hand fell across the tibial artery, where I noticed a strongly-marked Corrigan pulse. The sensation to my hand was as if a tight cord were snapped up against the palm and suddenly withdrawn from the same. This pulse is pathognomonic of aortic insufficiency, and on auscultation Dr. Chamberlain and I thought we could distinguish an aortic regurgitant murmur, but the coarse mucous râles above referred to were so noisy that it was difficult to settle the question. Our confidence in the significance of the Corrigan pulse was so great, however, that we diagnosed aortic valvulitis, with resulting insufficiency, as the trouble in the heart.

March 13th. Rapid superficial breathing. Profuse sweating of head. Slight increase of reflex movement on tickling feet. Scowls if face be pressed. Entirely oblivious of everybody around him. Urine passes unconsciously. No movement of bowels for four days.

Nothing was retained on stomach for previous forty-eight hours. Peculiar sweet death odor noticeable on entering room. Died quietly at 4.30 p. m., that is about eleven days after beginning of cardiac attack, as nearly as can be reckoned.

The autopsy was made by Dr. W. F. Whitney on the next day, with the following result:—

Autopsy twenty-four hours after death. Ice had been placed on abdomen. Body of a very large man. Rigor mortis absent. Head not opened. Subcutaneous adipose tissue largely developed. Large amount of fat deposited in omentum and mesentery. Otherwise nothing abnormal in peritoneal cavity.

Pericardium normal. Heart enlarged. Walls of left ventricle three eighths of an inch in thickness; of right ventricle one fourth of an inch. Color of muscle light reddish brown. Microscope showed no change in muscular structure. The free edges of the mitral valve slightly thickened and irregular, of a yellowish-white color. No evidences of recent disease. The aortic valves showed insufficiency by the hydrostatic test. The free edges of the valves were irregular in outline, showing a marked loss of substance. The curtains of the valves were slightly reddened, and on the surface, especially near the edges, was a yellowish-white deposit, mixed with recently-clotted blood, and on which small whiter specks were to be seen. These were found to be composed of minute round bodies (micrococci) larger than the granular detritus which composed the mass of the substance covering the valves. The right heart presented nothing abnormal.

The right lung was bound to the chest wall by moderately firm adhesions. The lung did not collapse on removal from the body, and was of a dark reddish color. Upon section a reddish fluid, mixed with bubbles of air, could be pressed from the cut surface, which was homogeneous throughout. This was especially marked in the lower lobe.

The left lung presented the same appearance, though to a less degree.

The spleen was of twice the normal size. On section the pulp was found to be of a dark-reddish color, and very soft.

The kidneys were increased in size, soft. The capsule slightly adherent in places. On section the cortical substance was slightly increased in thickness, and was of a slightly opaque yellowish-white color, not uniform, but giving it a streaked appearance. The outline of the separate cells, under the microscope, was not to be distinguished, and their bodies were filled with a fine granular substance.

The liver was large, of a lightish-brown color, the acini distinct from each other, but the surface had an opaque look, and was rather dry. The outline of the cells was more rounded than normal. Some of them contained well-marked fat drops, but the larger number contained fine glancing particles, not turning black with osmic acid.

Other organs presented nothing unusual.

Diagnosis: Acute ulcerative endocarditis. (Edema of lungs and hypostatic congestion. Cloudy swelling of liver and kidneys. Acute splenic tumor.)

If we exclude the cyanosis, which, of course, would make one think of the heart, we notice in this case the conspicuous absence of any symptoms pointing to that organ until the destruction of the aortic valves was revealed by the Corrigan pulse. There was no præcordial pain or oppression in breathing, and the

patient presented rather the appearance of typhoid fever than of heart disease. There is no doubt but that this trouble is often mistaken for ague, pyæmia, enteric fever, subacute rheumatism, or tuberculosis. The beginning of the disease is always obscure. It may be ushered in by a chill or even a rigor. The pulse is then quickened, the tongue dry. Fever is a conspicuous symptom, and the temperature may rise to 104° or 105.8° F., but may also run at a lower level. The temperature often assumes a pyæmic type of irregular fluctuations, which is a very important symptom. The pulse is always rapid, 120 to 160. There may be jaundice, and articular pains are often complained of. Vomiting and diarrhea are common.

These symptoms are general, and point in no particular direction. But now follow a series of phenomena which are very characteristic. Ulcerative endocarditis is distinguished by an accumulation of septic vegetations upon the endocardium, or upon the valves of the heart. These vegetations are soon torn from their attachments, swept away, and distributed among all the organs of the body. Lodging in the skin, they produce petechiæ, and even large purpuric blotches. In the spleen they cause enlargement and softening, with tenderness to pressure. The kidneys become inflamed and swollen, and albumen appears in the urine. Emboli in the brain produce all degrees of cerebral aberration, from muttering delirium to somnolence and coma.

This series of successive explosions of nutritive and functional disturbances in numerous and remote organs, combined with great physical prostration, and possibly with pyæmic fever, are the chief symptoms which lead us to suspect this disease. Of course, the case becomes immensely simplified if we obtain evidence of recent valvular changes in the heart itself. But the first point is to suspect the heart, and to examine it frequently. Dr. Thompson says whenever he finds a murmur or medley of murmurs at the præcordium, combined with delirium, he thinks of embolism of the extreme arterioles of the brain, and especially in the cortical substance of the convexity.

The conditions under which this disease occurs are as uncertain and ill-defined as are the symptoms which accompany it.

My case was preceded by sciatica, and the disease sometimes follows rheumatism. Dr. Osler¹ found that out of fifty-seven cases 26.3 per cent. were associated with rheumatism. The disease may occur spontaneously, and no possible cause he discovered for it, and again it may be superimposed upon an old valvular trouble. It is occasionally secondary to some inflammatory focus. Again one case is reported where it was associated with a suppurating corn on the foot.

The nature of ulcerative endocarditis has long been the subject of discussion and experimentation. Virchow detected, many years ago, a difference between this and ordinary endocarditis, seeking an explanation of this difference he cut up various substances and injected them into the veins of an animal. Bits of caoutchouc simply produced the ordinary results of mechanical obstruction to the circulation, while animal substances (bits of muscle, fibrin, etc.) caused severe inflammation, suppuration, and sloughing. Virchow therefore concluded that the phenomena of infection were due to chemical changes in the emboli. Others

¹ Recent Progress in the Theory and Practice of Medicine. By G. B. Shattuck, M. D. Boston Medical and Surgical Journal, March 31, 1881.

followed this idea in assuming that the irritant effects are due to the decomposition of the emboli which plug the vessels. Lanceraux thought the poisoning was caused by an alteration in the connective tissue of the valves themselves, and not by disintegration of the vegetations alone. Virchow noticed that the valvular deposits contained fine closely-packed granules, which were insoluble in potash, acetic and hydrochloric acids, but were dissolved in chloroform. He considered them to be of a fatty nature.

Professor Winge was the first one (1869) to advance the theory that these granules are living organisms, and he called the disease mycosis endocardii. This same view was taken by Professor Heiberg, of Christiania, who sent specimens to Virchow for examination. With further study Virchow, Klebs, Koster, and a number of other Germans have given their approval to this theory, and they say that the organisms found are micrococci, vibriones, bacteria, and leptothrix filaments. Some of these observers believe that the germs are the essence of the disease. Heiberg inclines to the germ side of the question, but he allows that cases of ulcerative endocarditis present themselves wherein no parasites can be detected. Eberth thinks that the bacteria are introduced into the blood from without, and become aggregated into a sticky mass, which adheres to the surface of the cardiac valves. Here they multiply rapidly, and, dropping off, are distributed to all parts of the body. On the other hand, some writers repudiate the germ theory with great vigor, and claim that the parasites, if present, are merely the accidents of the disease. Miller says that bacteria and leptothrix are constantly present in the healthy mouth, and if they are so dangerous we ought to be poisoned all the time. He thinks the granules described are merely detritus.

Examining a case of ulcerative endocarditis after death, one finds one or more of the valves and portions of the endocardium covered with patches of vegetations and ulcerations. These patches are generally small in area, and may be on either side, and in any one of the four chambers of the heart. Of course, when the disease is limited to the right side of heart the brunt of the embolic explosion comes upon the lungs, which usually contain scattered abscesses. The liver is pale and flabby. The spleen is soft and pulpy. The kidneys present cloudy swelling, and hemorrhages may be seen in any or all of the chief organs and tissues. Dr. Hall Curtis¹ reports a case where small spots of superficial gangrene formed on the right leg from minute emboli in the skin.

Little can be said in regard to the treatment of this formidable disease. Nearly all the cases reported have been fatal, and some were rapidly so. I have seen one doubtful case of recovery described, but it seems as if our chief consolation in this disease will be the satisfaction of having detected its presence before it was revealed by the autopsy.

— On the first day of the American Medical Association, by request of Dr. Gross, the rules were suspended to allow Dr. Gross to make a motion for the establishment of a section of dentistry. The motion was seconded by Drs. Sayre and N. S. Davis, and was adopted without a negative. The section is to be in working order at the next annual session.

THE NECESSITY OF THE LONG NOZZLE IN MAKING INTRA-UTERINE INJECTIONS AFTER CONFINEMENT.²

BY EDWARD JACOB FORSTER, M. D., CHARLESTOWN, MASS.

In cases where there remains in the uterus after confinement any clots, portions of the placenta or membranes, which by undergoing decomposition may be the source of septicæmia, the use of the common vaginal tube or nozzle sold with the ordinary bulb injection syringe has, I am convinced by observation, been the cause of giving general practitioners a false sense of security, that by their use, they were doing all that was necessary to disinfect the uterine cavity and combat the tendency to septicæmia. Such a tube should never be used unless the point is made to enter the os, and is carried well up to the fundus. A neglect to thus reach the fundus may be and is the cause of fatal consequences, as two of the cases which I report this evening will, I think, clearly show.

The Davidson Rubber Company have made a tube twenty-seven centimetres long (about ten and one half inches), resembling the ordinary one except in length and the direction of the openings: the latter is only eleven centimetres (or four and one half inches). They have also, at the suggestion of Dr. Wm. L. Richardson, made a tube (here represented) of the same

length as the first, that is, twenty-seven centimetres, in which the openings are so pierced that the stream is recurrent and the holes make a spiral turn about the tube, and thus wash thoroughly every part.

Some of these have been made which have at the end which joins the rubber tubing a joint so that they can be turned while *in situ* without at the same time turning the bulb.

One of these long nozzles should be in every obstetrician's bag.

In certain positions of the uterus the joint cannot be used. The tubes are made of block tin, and can be bent to any reasonable extent deemed necessary. Tubes of a poorer quality are made of lead nickel plated, and when bent the plating cracks off.

CASE I. While at dinner on the evening of Monday, the 18th October, 1880, I was called suddenly, in the absence of the family physician, to Mrs. X., thirty-four years of age, primipara, who was supposed to be at full term. I found her lying upon the bed, dressed, unconscious, with head thrown back, eyes protruding, and violently convulsed.

Ether was immediately given, and the following history obtained: The waters had broken five days before; the amount of urine passed during the last few days had been notably diminished; the patient having had severe headaches, had just before the convulsive seizure complained of great pain in the head.

An examination per vaginam showed the cervical neck patulous, but otherwise as in the eighth month. Assistance was asked for, and Drs. J. G. Dearborn and R. A. Blood responded.

The necessity of emptying the uterus of its burden, and thus relieving the kidneys of the mechanical pressure under which they were attempting to perform

² Read before the Obstetrical Society of Boston, March 12, 1881.

their function, was acknowledged by all present, and the induction of labor by manual dilatation was agreed to. Dr. Dearborn took charge of the anæsthetic, and Dr. Blood and myself undertook the dilation, working alternately.

The vagina offered the most resistance, for when the whole hand had reached the os it was easy work to dilate it. After deliberation it was decided to complete the delivery by the forceps.

I applied one blade, but a sudden crick in my shoulder prevented me from passing the second. So the application was finished by Dr. Blood, who locked and passed them to me, but before attempting delivery the physician who had been engaged to attend the case made his appearance, and I immediately offered them to him. Taking the forceps he at once extracted a rather small female, the cord pulsating strongly. All attempts made by the family physician to resuscitate the child failed. After giving him the history of the case up to the time of his arrival, I left the patient in his hands.

I learned, accidentally, that on Wednesday, two days after delivery, the patient had a chill.

Four and a half days after delivery I was called about four o'clock in the morning by the husband, asking me to see the case in consultation, saying that the attendant had given an unfavorable prognosis.

I found the patient delirious, pulse 104, full and strong, abdomen tympanitic and tender over the fundus which was high up. The skin was said to have a yellowish tint which, however, did not appear in the gas-light. There had been diarrhœa, for which opium had been given; the temperature was 102° F., and had never reached a higher figure.

Quinine and stimulants in large doses, with antiseptic injections every three hours, I think, had been the treatment pursued. The time for an injection being at hand I asked and was accorded permission to see one given; the nurse gave the injection with a fountain syringe, the common vaginal nozzle being used, the proximal end not passing the vulva. The nurse, in answer to my query if she always gave the injections and in that manner, replied in the affirmative.

Retiring with the attendant I agreed to the quinine and stimulants, and suggested that he give the injections himself, passing the tube well up, to which suggestion he acquiesced.

Later in the same day I was requested to see the case again and meet Dr. William L. Richardson at 11.15 A. M.

At that hour the attending physician, Dr. Richardson, and myself were present. The patient's condition was much the same as in the early morning. On examination Dr. Richardson found the perinæum had been ruptured and stitched but the wound appeared well. The cervix was found to be torn in two places and the cavity of the uterus filled with old clots and decomposing *débris* of a very offensive character. The physician informed us that three hours before he had thoroughly cleansed the uterus.

Upon retiring to the parlor Dr. Richardson advised a thorough syringing and cleansing of the uterine cavity, a continuance of the brandy and quinine, and thought that the diarrhœa was an effort of nature to eliminate the poison and should not be checked. He gave an unfavorable prognosis.

At about six P. M. I was informed that the attendant had been dismissed and was asked to take charge of

the case. After some hesitation I assented, and soon after had Drs. Richardson and Blood in consultation.

We at once thoroughly washed the uterine cavity, the first returning fluid being very offensive and containing putrescent matter. The catheter was also passed, but, owing to the eyes of the instrument becoming clogged with diphtheritic membrane, several attempts were necessary before a tablespoonful of urine was obtained. The patient was soon unable to take stimulants, the temperature rose rapidly, and death ensued at 11.15 P. M.

An examination of the urine showed it to be highly albuminous, and every field examined was filled with coarsely granular and fatty casts and blood cells.

CASE II. On the 27th of November, 1880, I was called to a neighboring town to see in consultation Mrs. Y., twenty-six years of age, primipara, who a week before had been delivered of a female child after an easy and natural labor.

When seen the patient was unconscious, pulse too rapid to be counted, temperature 102° F. No tympanites. The nurse remarked that the lochia had less odor than usual, no offensiveness having been noticed. Three days after the confinement the attending physician noticed the uterus much enlarged and informed the nurse that in all probability some clots would shortly come away. Stimulants were being given but sparingly, a tablespoonful of brandy only in the twenty-four hours.

A daily antiseptic injection had been given by the nurse with the ordinary nozzle, and no offensive odor had been noticed.

Making a vaginal examination I found the cervix torn and my finger covered with the most offensive fluid I have ever encountered.

Using the long nozzle which I have described, I brought away large quantities of the same offensive matter, and continued the injections until the returning fluid had no longer any odor but that of the carbolic acid which it contained. Hypodermic injections of brandy were given, notably strengthening the pulse for a few moments. The case, however, soon terminated fatally.

In contradistinction to the foregoing unfortunate cases the following is reported.

CASE III. In the evening of the 9th of December, 1880, I was called in consultation to see Mrs. Z., multipara. The patient was a stout Irishwoman. An examination showed the head engaged in the superior strait, the face to pubes, the cord prolapsed, and the anterior lip well down. She could not be made to assume the face and knee position, and all efforts to return the cord were unavailing.

Ether was absolutely refused. The forceps had repeatedly been applied and as often slipped. At a second visit, an hour or more later, after much urging, consent was obtained to administer ether, and I at once took charge of the anæsthetic.

In one of the attempts to extract the child the forceps again slipped, and the cord was broken in two. The head was finally brought down, and with it there appeared at the vulva what the attending physician who first saw it thought to be the congested urethra and meatus, which had prolapsed; examination showed it to be the greater portion of the anterior lip, all but separated from the uterus, lying antero-posteriorly in the vagina, and resembling in size, shape, and color, a small Bologna sausage.

Antiseptic injections with the long nozzle were given at once and continued; the anterior lip sloughed off in a few days, the patient making a good recovery, with scarcely an untoward symptom.

While Cases I. and II. are reported to show that the common vaginal tube gave a false sense of security, there are other points which are open to adverse criticism.

The use of forceps in such cases as No. I. was formerly taught, but latterly authorities advise delivery by turning as preferable in rendering the accidents mentioned less likely to recur. In the light of my experience in this case I should, under similar circumstances, practice turning.

The importance of recognizing some slight lacerations of the perinaeum, as insisted upon by Dr. G. H. Lyman, and the necessity of operating at the earliest possible moment, should cause an early examination of and attention to such injuries.

In regard to the checking of the diarrhoea by opium, Dr. Armstrong, writing of Puerperal Fever in 1849, says that he found a diarrhoea coming on in the first stage sometimes carried off the disease; on the contrary, constiveness was always an unfavorable circumstance.

In Case II. the sudden enlargement of the uterus on the third day, which the attending physician rightly interpreted to be due to a clot, should at the same time have suggested the necessity of at once removing it.

In both cases the injections were at first given by the nurses, an operation which should only have been done by the physician.

Dr. Edward W. Jenks, in his article on Intra-Uterine Injections for Septicæmia,¹ gives his opinion strongly upon this point, saying:—

"The administration of these injections ought never to be intrusted to a nurse or inexperienced assistant, but should invariably be given by the accoucheur himself, with as much carefulness and attention to every detail as he would exercise in the performance of a surgical operation."

In the discussion which followed the reading of his paper, Dr. Fordyce Barker, speaking of these injections, said "they should never be trusted to a nurse," and Dr. T. G. Thomas added that he never intrusted this delicate duty to one.

The principal objections to using these injections after confinement are:—

I. The alleged danger of air being made to enter the uterine sinuses.

II. The alleged danger of the fluid entering the peritoneal cavity through the open Fallopian tubes.

In regard to the first, if the tube is filled with the antiseptic fluid this accident cannot happen. In regard to the second objection, the tubes or nozzles here described lessen the danger of forcing fluid through the Fallopian tubes, the direction of the openings being reversed from those in the ordinary vaginal one.

In using this tube for vaginal injections in the non-puerperal state, this distal opening is again dangerous, as fluid may unintentionally be forced into the uterine cavity. At the suggestion of physicians the company have discontinued making the central aperture.

In using intra-uterine injections in the treatment of septicæmia, and of their value I am thoroughly convinced, we cannot do better than bear in mind the following precautions given by Dr. Jenks:—

"(a.) The mouth and neck of the uterus should be well dilated, and a free outlet insured for the injected fluid.

"(b.) Air must not be admitted with the injection.

"(c.) The fluid should be injected slowly, and without much force.

"(d.) The fluid used for injection ought not to be of a lower than the normal temperature of the body."

RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

E. G. CUTLER, M. D.

CHANGES OF THE SALIVARY GLANDS IN HYDROPHOBIA.

THOUGH the infective character of the saliva in hydrophobia is well known, there have been hitherto no positive descriptions of the changes met with in the salivary glands of animals affected with this disease. It is stated, indeed, that the glands are found to be in a hyperæmic condition, though Bruckmüller contradicts this statement. The observation of Nepveu² throws a little light on this subject. He found a tolerably extensive small-celled infiltration of the interstitial tissue in the salivary glands of a boy seventeen years old, who died of hydrophobia. Elsberg³ gives the chief results of his investigations undertaken on twelve dogs and two human beings affected with the disease.

In the dog he found the greatest change in the submaxillary and sublingual glands. The former was slightly enlarged, presented a smooth surface on section, with here and there indistinct acinous structure, and had a grayish-red color. Examined with the microscope there was a considerable infiltration of the interstitial tissue, with small cells having one or several nuclei, and resembling precisely the colorless corpuscles of the blood. This infiltration was greatest about the excretory ducts and veins of medium calibre in the hilus of the acinus; it diminished gradually towards the periphery, and at the hilus of the gland it was entirely absent. At times the infiltration of the acinus assumed such dimensions as to represent microscopically a collection of pus. The infiltration in the interacinous tissue was very much less.

The fixed cells of the interstitial tissue were slightly enlarged, swollen up, without a trace of division.

The blood-vessels, particularly the small veins and capillaries, were much dilated, and the blood filling them contained a large number of white corpuscles lying both irregularly distributed amongst the red corpuscles and also next the wall of the vessel.

The epithelium of the alveoli of the submaxillary gland as well as the crescent-shaped cells (Lunulæ Gionuzzi) also did not remain unchanged. The contents of the secretory cells first became slightly granular instead of consisting of a transparent, slimy mass, the granular mass gradually increased, while at the same time the circumference of the cell diminished one third. The nucleus became rounder, increased in size, and its former peripheral position became a more central one. Such cells were readily stained by pikro-

² Gazette Médicale de Paris, 1873, No. 47.

³ Centralblatt für die medicinischen Wissenschaften, March 26, 1881.

¹ Volume IV. of the Transactions of the American Gynecological Society.

carmine or hamatoxyline, and occasionally two nuclei were seen in them.

The crescent-shaped cells swelled up, sometimes enlarged so much as to fill up two thirds of the entire alveolus. At the same time the number of their nuclei increased considerably, so that one found in a crescent-shaped cell three and more times as many nuclei as in a normal cell.

In addition to the above changes an inconsiderable number of small round cells, analogous to white blood corpuscles which had pushed in from the neighboring interstitial tissue, were sometimes seen in the glandular alveoli. The same appearance was also met with in the excretory ducts of middle calibre. The small cells piercing the wall lifted up the epithelium, separated the single cells from each other and got into the interior of the duct.

A moderate infiltration of small cells occurred about the nerve ganglia, and sometimes it even penetrated the ganglia.

Similar changes to those in the submaxillary, though of less intensity, were found in the sublingual gland.

The orbital gland of the dog, which, like the two former, belongs to the same group of mucous salivary glands, was always very slightly altered.

In these three glands Elsenberg always found the changes described above; the parotid showed only in four dogs inconsiderable alterations. The small-celled infiltration of the interstitial tissue was always moderate; the gland cells were a little enlarged, appeared granular, and contained two and more nuclei. Similar changes to those in the gland cells were observed also in the epithelium cells of some of the excretory ducts of medium size.

In the human subject Elsenberg found no changes at all in the parotid, in the submaxillary only very slight ones, confined to a small-celled infiltration of the tissue surrounding the excretory ducts and medium-sized veins, while the most marked alterations were met with in the sublingual, and were similar to those found in the dog, though less intense.

These changes convince Elsenberg that there are disturbances of circulation and nutrition which may be regarded as inflammatory. The cause of this inflammatory process is the infectious material which circulates in the blood, and is eliminated by the saliva.

Since the greatest changes affect the submaxillary and sublingual glands, and, on the other hand, the mucous glands at the base of the tongue are very rarely found to be altered, it may be affirmed that the saliva of the submaxillary and sublingual glands chiefly, perhaps exclusively, contains the specific infectious material of hydrophobia.

The alterations of these two glands render it possible to diagnose hydrophobia in the dog, since they occur only in this disease.

Diseases of the salivary glands in animals are altogether very rare, and such have not hitherto been described in dogs. Many alkaloids, as nicotine, pilocarpine, and muscarine give rise to a few changes in them, but they are so slight as to be scarcely mistaken for alterations such as have been seen by Elsenberg in hydrophobia. In the human subject these glands present slight and therefore for hydrophobia little characteristic changes, since similar alterations also occur in people after different infective diseases, and, moreover, many medicines in frequent use give rise to similar and quite as slight disturbances.

THE RESULTS OF LIGATURE OF THE URETERS AND RENAL ARTERIES IN ANIMALS.

Popoff¹ gives the results of eleven experiments performed on animals. He ligated the ureters five times in dogs, and the renal arteries an equal number of times, and further he tied the ureters once in a rabbit. Two of the animals died of hæmorrhage and one of peritonitis, all the rest died in consequence of stopping the secretion of urine two or three days after the operation; the symptoms being those which are usually designated as uræmic. The clinical appearances observed in the uræmic animals in ligature of the ureters and of the renal arteries were partly alike and in part different from each other.

The gross appearance of the *brain* and its membranes in almost all cases was a greater or less degree of hyperæmia, chiefly of a venous character; sometimes also there was observed in the brain in comparison to the normal a somewhat greater amount of fluid, so that it appeared to be moister and softer than usual. With the microscope a net-work of capillaries and also larger vessels was apparent, characterized by the presence in or near them of more or less refractive, almost colorless, or faintly yellow or greenish hyaline masses of variable size, from that of a red blood corpuscle to three or four times as large. These masses were either single or in groups, and could be seen in fresh brains or, better, after hardening in bichromate of potash, Müller's fluid, or chromic acid. With a high power (Hartnack ocular three, objective seven) these masses were very frequently seen to be situated outside the vessel in the so-called perivascular lymph space; moreover, in most cases, they were found at the point of division of the vessel. Their accumulation at these places might be so great as to completely compress the lumen of the vessel. Inside the vessel they were found either in the walls between the different layers, especially between the fibres of the adventitia in the so-called intra-adventitial lymphatic courses, or in the lumen of the vessel itself. When situated in the wall of the vessel there was a certain regularity of their position, as they lay in the spaces of the connective tissue where the fixed connective-tissue corpuscles were, or suggested the position of the nuclei in the capillaries. This accumulation of hyaline masses, both between the elements of the wall of the vessel, in the lumen, and outside of it, must naturally present a very considerable obstruction to the free circulation of blood; in many cases it may, indeed, entirely interrupt it, and thus cause very considerable functional disturbances of the brain. On carefully examining the bodies described above many of them, both in appearance and size, greatly resemble red blood corpuscles, though without the double contour of the latter. Their color, also, sometimes did not vary much from red corpuscles. Some elements, however, though exhibiting similar characters, were much smaller than red blood corpuscles, suggestive of a partial dissolving of the same; and others, again, considerably larger, indicated a swelling of them. They differed from fat drops both optically and chemically. Addition of alcohol and ether changed them and dissolved them partially only, thus showing that they were not fat and distinguishing them from colloid masses which it is well-known are insoluble in alcohol and ether. Osmic acid gave them a darker color than the rest of the elements of the brain tissue, yet this staining was not so energetic, and did not appear so black, as is usually the case with fat. Fur-

¹ Virchow's Archiv, vol. lxxxii., p. 40.

thermore, like iodine, osmic acid broke up the larger masses into the smaller elements of which they were composed.

Popoff draws the conclusion that the hyaline masses above described are really red blood corpuscles in a state of metamorphosis.

In the liver a considerable amount of fat was found in the connective tissue which accompanies the hepatic capillaries; it was seen more especially in the branched cell of the connective tissue. Besides the occurrence of fat in the liver there was usually a granular change of the hepatic cells sometimes attaining a high degree. Acicular crystals formed very readily in sections examined in glycerine.

Among the appearances in the *kidney* after ligation of the ureters was especially increase in volume and hemorrhage into the capsule and surrounding connective tissue and partially into the kidney itself. The organ in most cases was in a more or less pronounced condition of anæmia, especially in the cortical portion. On section usually a considerable quantity of yellowish watery turbid fluid flowed out and in such cases the pelvis was considerably distended by urine; microscopic examination showed the capsules of the Malpighian bodies to be in the same condition, and the vessels of the glomerulus to be pushed aside. The epithelium of the tubules, especially the convoluted ones, was for the most part very granular, some of them showing a marked fatty or colloid degeneration. In the lumen of both convoluted and straight tubules various crystals are frequently met with, the chemical nature of which requires special investigation. The kidneys whose arteries were ligated appear somewhat diminished in size or shrunken. The cortical portion had a very striking grayish-yellow color, and was sharply bounded from the dark-red medullary portion which usually exhibits a general venous hyperæmia. Microscopic examination showed a high degree of fatty degeneration of the urinary tubules of the cortical layer.

The *spleen* showed no special change in either set of experiments. The *stomach* and *intestines* in both cases presented the appearances of a more or less considerable catarrh. Usually the *heart* was filled with abundant firm coagula, its tissue had a grayish color and was flabby, and the muscular fibres often appeared decidedly granular under the microscope. The *pericardium* and *pleura* were often hyperæmic, and not rarely small ecchymoses were found in them. The *lungs* usually exhibited no special change. The *muscles* of the body and extremities were usually of a very pronounced dark-red color, and with the microscope often showed a greater or less marked granular degeneration, like that of the heart.

To formularize the symptoms:—

(1.) The animals in each case lived about the same length of time. Almost always death occurred in the course of the third day; in ligation of the ureters a few (four to five) hours later.

(2.) The chief phenomenon, which in both cases occurred soon after the operation, was sinking of the temperature. The use of narcotics during the operation, as chloroform, morphia, or opium, made the depression of the temperature more marked (on the first day), but could not be regarded as the cause, since the temperature also fell in cases where no narcotics were used. This fall of the temperature, while it fluctuates only a little at first (especially on the second day), becomes more considerable as time goes on. Inflammatory com-

plications, as of the peritonæum, may exercise an influence on the height of the temperature and raise it a little; nevertheless it sinks even here below the normal.

(3.) Besides falling of the temperature, diminution in the frequency of the pulse was often observed (the strength of the pulse was not diminished, at least at first).

(4.) Vomiting and diarrhœa, sometimes accompanied by blood, were observed in both cases.

(5.) Most constant and characteristic, in all the animals operated on, were the appearances of relaxation and somnolency, which generally ended in coma.

(6.) Tonic and clonic convulsions were very often present, and strongly marked in ligation of the ureters. They were only observed in one case after ligation of the renal arteries, and then only very slightly marked.

It was found that the crystals observed in the liver were due to the storing up of urea in that organ. They were observed more especially in ligation of the ureters, and were not constant in ligation of the renal arteries.

Csokor, Adjunct and Docent in the Veterinary Institute in Vienna, in a late number of Virchow's *Archiv*, calls attention to the fact that the changes described above by Popoff, as occurring in the brain after ligation of the renal arteries and ureters, are met with in healthy dogs, and are to be regarded as indicative of a normal senile change which occurs in the brain of every dog.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DR. GAY.

REPORTED BY DR. J. N. BULLARD, HOUSE SURGEON.

COMPOUND COMMINUTED FRACTURE OF ELBOW-JOINT: EXCISION.

CASE I. Frank M., nine years of age, fell from a fence, September 3, 1880, striking directly upon the left elbow. On entrance, a small opening was found over the external condyle, large enough only to permit the passage of a probe, which impinged upon the bone. The elbow was much swollen and distorted; the external condyle appeared to be displaced downward, the internal condyle not being made out. The patient being etherized, an incision was made, under Lister spray, three inches long over the external condyle. The lower end of the humerus was found to be denuded of periosteum and comminuted into three pieces, the internal condyle being forced downwards back of the olecranon, with the external condyle displaced downwards and forwards, there being a third smaller fragment resting in the head of the ulna. The humerus was excised about two inches above the condyles, the periosteum, however, being torn from the bone for a distance one and a half inches higher than this. The wound was carefully washed with carbolic water and dressed with Lister gauze, and the arm laid in a straight position on an oakum pillow.

September 8th. Dressed on alternate days under the spray. Discharged considerable. Edges of wound healing slowly.

September 25th. Not having improved was etherized and an incision made two inches long over inner aspect of arm. A single flow of pus followed, a drainage tube was passed through to the other opening; wound was directed to be syringed through and dressed every other day under spray.

October 1st. Patient was etherized and under spray the external opening was enlarged and nearly two inches of the humerus, bared of periosteum and roughened, was removed. Dressing of Lister gauze continued.

October 25th. It was healing rapidly. Inner wound was entirely closed. Very little purulent discharge. Lister dressing continued.

November 3d. Dressed with zinc ointment. Patient gets up.

November 16th. Arm all healed but a little point of granulation over outer side, through which the probe passes to dead bone. Uses arm very well, can touch with his fingers his forehead but not his nose.

November 27th. Condition as above. Is discharged at own request.

COMPOUND COMMINUTED FRACTURE OF ELBOW-JOINT: EXCISION.

CASE II. Lawrence H., aged ten, was struck by a horse-car in crossing Washington Street, September 26, 1880. On entrance was etherized. Examination showed a piece of skin two and one half by three inches forcibly torn away from over the inner condyle and anterior aspect of the arm. A small opening here existed leading into the joint. There was a T fracture of both condyles, the external being displaced downward upon the head of the radius. The olecranon was completely broken off. Under the spray, an incision was made in line of the olecranon and the end of the humerus sawed off. The head of the radius and ulna were also removed, the insertion of the biceps not being destroyed. Very little hemorrhage. Washed with a strong solution of carbolic acid and drainage tube passed through. Lister dressing applied.

November 29th. Some sloughing about the edges where skin was torn away, and a slight redness extending up the arm. Dressed under spray every other day, each dressing causing him considerable pain.

October 26th. Edges granulating slowly. The opening into joint has entirely closed, the tube being removed ten days ago. Considerable purulent discharge from granulations.

November 5th. Lister dressing omitted and zinc ointment substituted. Discharge much less. Healing fast.

November 13th. Gets up with arm in sling. Granulating surface nearly closed.

December 14th. Arm entirely healed for some time. Very fair motion at joint. Can swing arm forward but cannot touch the top of his head nor his face. Discharged well.

NECROSIS OF ELBOW: EXCISION: DEATH.

CASE III. M. G., a scrofulous looking young man of twenty-one, from Prince Edwards Island, entered hospital October 25, 1880, with following history. One year ago his elbow became sore and swollen from no known cause. Abscesses had formed and broken and showed no tendency to heal. The elbow had slowly enlarged and became stiff. There are now several sinuses leading to dead bone about the joint. At the

middle of the forearm was an opening apparently superficial, discharging pus. Patient was put to bed with poultice for elbow, and treated with tonics and extra diet.

October 29th. Etherized, and under the spray, an incision was made over the olecranon. The ulnar nerve was reflected to the inside and muscles and tissues dissected away from the bones. The bones were roughened, and surrounded by a jelly-like material. Three inches of humerus and two of the radius and ulna were bared and removed. A drainage tube was put in, the opening on the forearm enlarged, and the arm dressed with carbolic gauze.

November 3d. Has been dressed daily. Considerable suppuration with pus burrowing about the arm. Suffers from no pain. Temperature reaches 102° F. in evening with morning remission.

November 15th. Wound dressed with soda wash under carbolic gauze. A few small abscesses have formed about the wound and discharged pus. Granulations looking well.

November 30th. Has been dressed with weak solution of nitric acid. Wound looks healthy.

December 7th. Temperature running to 105° F. every night. Very little discharge. Brandy, five ounces daily.

December 13th. Has been very stupid and quiet of late. Is passively delirious. Takes very little nourishment. Tongue dry, brown. Fingers of right arm tonically contracted. Temperature 105° F.

December 18th. Has been slowly failing of late. Has to be roused for food, of which he takes but little. Very little suppuration.

December 20th. Died 8.20 P. M.

CASES OF TRACHEOTOMY.

CASE I. Willie D., aged six, entered hospital October 3, 1880. Suffering from severe dyspnoea. His skin is purplish, respiration quick and labored, with deep retraction of intercostal spaces. Discharge from nostrils constant, but no bleeding. No membrane can be seen in his throat, although his brother, aged eight, who entered with him, had well marked patches upon both tonsils. No swelling about the neck. Administration of ether produced marked lividity of face. A spasm of the glottis occurred before the trachea was opened, with cessation of respiration for a moment. Hemorrhage free, partly due to cutting vessels, partly to congestion of parts; this ceased on introduction of tube, and respiration became easy. The next day temperature rose to 101.5° F. Took nourishment well and breathed with no difficulty.

October 9th. Was troubled with cough and mucopurulent discharge which disappeared in two days more.

October 20th. Tube was finally removed, seventeen days after operation, all attempts to remove it before having been futile. Coughed some, and respiration had a croupy sound.

October 25th. Wound was entirely healed over, he breathed easily, voice was natural. Discharged well.

CASE II. Murtagh D., a feeble-looking child of eighteen months, entered November 2, 1880, with history of measles and whooping cough the past summer. Two days ago he developed symptoms of trouble in the throat. Examination showed the whole back of the pharynx covered with a diphtheritic membrane, thick and yellowish, respiration labored; pulse rapid and

weak. An incision was made, without ether, down to trachea, this was very soft and entered with difficulty. Patient collapsed for a moment after insertion of tube but soon rallied and breathed easily. Next morning patient had pulse of 160, with very rapid respiration. Refused nourishment. Failed rapidly, and died at 2.45 P. M.

CASE III. Ellen C., three years of age, entered November 21, 1880. One week ago caught cold but had no trouble till yesterday when she began to choke up. Her breathing is very labored with deep depression of intercostal spaces in inspiration. Face is livid, and pulse rapid and feeble. Etherized and tube inserted without difficulty, a large vein lying over trachea being drawn to one side. After ether, patient suffered with repeated attacks of coughing between which breathing stopped entirely. Pulse very rapid and feeble. Given enema of brandy two drachms. In three quarters of an hour breathing became easier and she was transferred to ward. Next day the neck was somewhat swollen, pulse and respiration rapid, would take but little nourishment. Failed rapidly and died at 4.30 A. M.

CASE IV. Joseph G., seven years of age, entered hospital November 23d on medical side, and next day developed measles. A younger sister had died at home, a short time previous, of membranous croup [?]. His mother entered hospital November 15th suffering with diphtheria, for which tracheotomy was performed. She died November 22d. By November 27th the eruption had disappeared on the boy and his tonsils became much swollen with a small white patch upon the right. Croupy cough and hoarse respiration, with swelling at the angle of the lower jaw. November 28th was etherized slowly, and trachea tube inserted without difficulty, considerable mucus being forcibly ejected on incision of trachea. Patient breathed easily afterwards. Pulse good. Given brandy, \mathfrak{ij} , in milk every four hours. Tr. ferri chlor. , gtt. iij. , pot. chlor. , gr. v. , every three hours. Next day the neck was badly swollen. Temperature 104, pulse rapid and feeble. Takes but little nourishment. Respiration was difficult and labored. Tube removed, when some pieces of tough, thick, membrane were coughed up. Tube replaced, and removed again later, but with no relief. Membrane was evidently invading the trachea below the tube; respiration became hurried and labored. All nourishment was vomited. Died of suffocation at two A. M.

[The most satisfactory manner of performing tracheotomy is as follows: The first incision is made by transfixing the skin with a narrow knife. By careful and repeated strokes in the median line the tissues, including the thyroid gland, are divided down to the trachea. The large vessels can usually be seen and avoided, the small ones require no special attention. The trachea having been seized on each side by a hook an incision is made between them, when the wound immediately opens sufficiently to allow of the introduction of the tube without the use of a dilator.

I no longer use a director in dividing the structures over the trachea, as in two instances, while making a careful dissection with the aid of this instrument, the cellular tissue became engorged with air and blood, the depth of the trachea was increased, and the operation was finished entirely by the sense of touch. In a small trachea the dilator takes up too much room, and, besides, the blades, not infrequently, get

between the rings of the trachea and fail to open the wound.

Unless the color of the skin is pretty good it is better to do this operation without ether. The pain is not great, and there can be no doubt that this agent obstructs respiration very much in patients enfeebled by great dyspnoea. It is said that chloroform relieves rather than increases the dyspnoea in these cases, but the prejudice against this anæsthetic is so strong in this city that one hesitates to make use of it. G. W. G.]

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

A. T. CABOT, SECRETARY.

FEBRUARY 7, 1880. DR. G. M. GARLAND reported at length a

CASE OF ULCERATIVE ENDOCARDITIS,

which appears in this number of the JOURNAL.

DR. F. C. SHATTUCK expressed himself as much interested in Dr. Garland's case, which brought to mind a recent case in the service of Dr. G. C. Shattuck at the Massachusetts General Hospital.

A man of twenty-three, previously in good health, entered the hospital November 25th with what seemed acute articular rheumatism, confined to the left knee, which was much swollen, painful, and tender. Five days before he had had a chill after decided exposure to wet and cold. Nothing abnormal was discovered about the heart or kidneys, and there were no remarkable developments in the case till December 1st, when two small abscesses were noted, one above the left elbow, the other on the outer aspect of the right thigh. During the night both testicles became swollen, hard, and painful, and then the left leg rapidly became the seat of a phlegmasia alba dolens. On this day it was noticed that the apex of the heart was visible inside of and on a line with the left nipple, and that a slight, short systolic murmur was audible in the region of the apex.

The following day this murmur was more distinct and longer. The patient grew steadily worse, the breathing became labored, and the lungs filled with rales. In the superficial cardiac space a sound suggesting friction was heard. The man died on December 7th, thirteen days from entrance into the hospital, and seven days after the first serious symptoms. The temperature vacillated considerably, but was never very high. All efforts to procure an autopsy were unavailing. The clinical diagnosis was acute rheumatism, pyæmia, and probably ulcerative endocarditis.

DR. PARKS said that he thought the disease was more common than might be supposed from reported cases. The cardiac symptoms appear late, and often are not characteristic. In a case seen at the Philadelphia Hospital there were no symptoms till near death, then those of pericardial effusion.

DR. F. C. SHATTUCK remarked that the disease known as ulcerative endocarditis is to be distinguished from ordinary endocarditis resulting in loss of substance in the valves and embolism, the difference being that the former is septic, the diseased products starting in the heart, and the emboli resulting from them being filled with micrococci, while the latter is relatively be-

nign. Endocarditis with ulceration is not uncommon, whereas he believes ulcerative endocarditis to be quite rare.

DR. WHITNEY said that in Dr. Garland's case there were no septic emboli. This disease is generally connected with some external injury or other means of septic absorption. In this case of Dr. Garland's there was but little evidence of rheumatism, and it would be interesting to know whether the joints were free from suppuration.

DR. GARLAND said that he regretted that the hip was not examined, but no clinical evidence could be obtained of any lesion there. Thompson calls the disease a form of pyæmia. Great fluctuation in the temperature is a marked feature in these cases.

FEBRUARY 21, 1881. DR. E. W. CUSHING spoke of an epidemic which had recently broken out among the cows in a herd at Cohasset. Among a large number three had been affected with an eruption on the udder. This appeared first vesicular, then pustular, and finally dried into scabs. Nothing of this sort had been noticed in this herd before, and it was supposed to be cow-pox.

DR. BOWDITCH thought the cases ought to be referred to Dr. H. A. Martin.

DR. CUTLER read a paper on a

CASE OF FIBRINOUS BRONCHITIS.

The patient, a lady of sixty-five, ordinarily enjoyed excellent health. During the month of February, 1880, she had a slight bronchitis, which did not confine her to the house, and for which she used only household remedies.

On March 4th, a cold, raw day, she walked some distance, and thought she added to her cold, as on returning home she had a sensation of chilliness, with fullness of the head. The next day and night she had considerable cough, with slight expectoration of saliva and some tough mucus. She felt, however, so little inconvenience as not to think the services of a physician necessary. On the following morning, however, March 6th, the friends, alarmed at her appearance, summoned Dr. Cutler, who found her sitting, dressed, in bed, but deeply cyanosed, and in a profuse perspiration. The pulse was feeble, 136, and the respirations 30. Percussion was normal throughout the chest, while auscultation revealed fine, dry râles over the whole chest. There were also coarse tracheal râles.

The diagnosis of diffuse capillary bronchitis was made. Brandy and carbonate of ammonia, which were already being given, were continued, and a large sinapism ordered to the chest. Dr. Cutler then went for other restoratives and professional aid, but on his return the patient was already dead.

The autopsy revealed the following condition of things:—

The pharynx and larynx healthy. The tracheal mucous membrane in its lower half was injected and slightly thickened. A croupous membrane lay reflected on itself over the entrance of the two primary bronchi. When laid in place this membrane reached less than half way up the trachea. Downward it extended into the minutest divisions of the bronchi, in many of them forming an almost solid plug. The alveoli contained no solid matter, and except in a few places where there was œdema or collapse they contained air.

DR. BOWDITCH asked whether the old treatment for dyspnoea, with strong emetics, might not have been of service in this case.

DR. CUTLER said that emetics were thought to be of use after the bronchial secretion has been increased with iodide of potash. In his case the membrane could not have been detached, extending as it did into the finer bronchi.

DR. BRADFORD showed some specimens of bones which he had obtained of Professor Putnam, of the Peabody Museum. These were from the mound builders or cave dwellers, and are known to have been from tribes existing before the arrival of the whites. These diseased bones had been picked from a thousand skeletons.

I. A femur with a perforation partially filled up and surrounded by evidences of suppurative osteitis. This may have resulted from some external violence.

II. Two tibiae. One normal, while its mate had evidences of caries of the ankle. An exostosis showed an attempt at repair. The possessor of this bone must have been long sick, requiring care, and must have gone about with some artificial support, as by cane or crutches.

III. Caries of the spine. The whole dorsal region was involved, and a cure by anchylosis had taken place. The rest of the skeleton showed the person to have been a young female. Years must have elapsed before the cure was effected, during which she must have required careful nursing.

IV. Two fractured femurs. The fragments were united in such good position that it seemed as if they must have been treated with quite considerable surgical skill. There was no bowing outwards or forwards, and but little rotation.

This position could not have been maintained till the cure was attained without some pretty efficient means of preserving the axis of the limb. The results would be considered good in these days in cases where extension could not be employed.

From the consideration of these specimens we must, then, believe that these Indians had some rude surgery and nursed their sick.

DR. TARBELL called attention to the fact that in the spinal case, notwithstanding the extreme deformity, the canal was not narrowed. This is a confirmation of the oft-observed fact that in spinal caries paralysis is due to inflammatory changes in the cord, and not to compression.

DR. JOSEPH STEDMAN reported the following case of

PERFORATION OF THE VERMIFORM APPENDIX.

A young girl, previously in good health, complained one morning of pain in the stomach, and at noon was unable to eat any dinner. At six P. M. she vomited a large quantity of food containing, among other things, tomatoes eaten five days previously, none having been taken since that time.

At eight P. M. Dr. Stedman was called, and found her complaining of pain in the neighborhood of the cæcum. Pulse much accelerated. The next day she was fairly comfortable, with a pulse of 100, temperature 100.5° F. Towards evening she vomited again, and had slight pain over the cæcum, with some tenderness. Opiates were given and fomentations applied. On the third day she was easy. Pulse about 100. Temperature 99° F. At his evening visit he found her doing well, and was about to leave the house

when she vomited about one half a pint of dark fluid like broken-down blood. Soon after she vomited again, and seemed on the point of dying, but lingered till the next morning.

Dr. FITZ, who made the autopsy, said that there was perforation of the appendix vermiformis about half an inch from the bowel. The appendix itself was peculiar in being enclosed in a fold of the omentum.

In regard to the advisability of opening the abdomen in cases of obstruction or obscure disease, Dr. FITZ said that recorded cases show great difficulty in arriving at the nature of the trouble after the peritoneal cavity is opened; even in autopsies it is often extremely difficult to unravel the conditions from which the trouble has resulted, and therefore one should be very cautious in recommending abdominal section in such cases.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, SECRETARY.

MARCH 26, 1881. Seventy-two members present. Dr. R. M. HODGES in the chair.

Dr. C. F. FOLSOM read a paper entitled

SOME POINTS IN THE EARLY DIAGNOSIS AND TREATMENT OF THE GENERAL PARALYSIS OF THE INSANE.

Dr. J. H. WHITEMORE said that during his residence at the McLean Asylum for the Insane he had only seen two cases in which there had been any reason to believe a cure had been effected. The first patient had been taken home by his friends, who felt sanguine of his having completely recovered. Six months afterward Dr. Whitemore learned that the delusions still existed, and there was little doubt that the disease would terminate fatally. The second was an inmate of the asylum several months, and went out very much improved. Dr. Whitemore had received that very day a letter, stating that he considered himself perfectly well; that he was engaged at present in light literary work, translating Latin and Greek for publication, and gaining his living thereby. The man's handwriting was very legible, and did not present at all the appearance it had when he was at the asylum, it being then considered very characteristic of the general paralytic.

Dr. T. W. FISHER spoke of the difficulty of obtaining general paralytics as patients in the beginning of the disease, especially in private practice. He had seen many cases in the early but many more in the later stages. It is almost invariably the case that the date fixed by the patient or his friends as that of the beginning of the disease is far from the true one. It is only by the most careful inquiry that this can be elicited. Dr. Fisher referred to five cases, three of which were supposed to be traumatic in origin. A careful inquiry into these would probably elicit the fact that they were tending to general paralysis before the injuries occurred. The condition of parietic patients in the earlier stages was such as to make them peculiarly liable to accidents, and the result was thus often considered the cause. Dr. Fisher spoke of a patient who had been under observation at the South Boston Asylum since July, 1878; his case illustrated the fact that illusions were sometimes present in the earlier as well as in the later stages. He had a great

variety of illusions and perverted sensations. Three days before death he had what is known as a congestive attack, during which, by mistake, an attendant administered some oat-meal gruel; this brought on a violent attack of vomiting and coughing, complete coma, extremely contracted pupils, stertorous breathing, and convulsions ensued. At the autopsy there was found thickening and opacity of the pia mater in patches; considerable clear fluid in the meshes of the pia; thickening and granular condition of the ependyma of the lateral and fourth ventricles; considerable diminution in the thickness of the gray matter of the cortex; diffuse yellowish discoloration of the thalami optici; acute desquamative pneumonia from inhalation of particles of food. Microscopically, increase in the connective tissue, fibres of the pia, with abundant round cell infiltration, more marked about the vessels; general pigmentation of the ganglion cells of the gray matter of brain and cord; infiltration of the adventitial lymph sheaths of vessels of brain and cord, with round cells and granular pigment. Considerable free pigment in the thalami optici. Hyperplasia of the connective tissue forming the ependyma of the ventricles with papillary-like growths of the same projecting into the cavity of the ventricles.

Dr. WHITEMORE, referring to one of the cases cited by Dr. Fisher, where the disease was claimed to have resulted from injury, said the friends had recently admitted that symptoms existed previously, not noticed at the time, but since recalled.

Dr. F. H. DAVENPORT read a paper entitled

A CASE OF URETHRISMUS OF TEN YEARS' STANDING CURED BY A SINGLE CATHETERIZATION.

"The severity of the symptoms and the marked effect of treatment made it of interest. The existence of a chronic spasmodic structure of the urethra is still, to some extent, a disputed question, that is, a cramp of the urethra lasting for years, present whenever an attempt is made to bring the muscle in question into play, simulating organic stricture, and giving rise to cystitis with its long array of symptoms; certainly this train of events is, to say the least, not fully recognized." Sir Henry Thompson says, "Spasmodic retention occurs seldom, and deserves special mention. Spasmodic stricture is an excuse when it is not possible to pass an instrument." Roser says, "What has been taught of spasmodic stricture rests on supposition against which much may be said." Bardeleben doubts if it can cause any hindrance to the passage of an instrument. Dittel thinks "it is certain that spasmodic stricture seldom occurs, certainly more seldom than it is diagnosed. I myself have never seen but one." Van Buren and Keyes state that it is of common occurrence, but unless complicating pre-existing organic stricture is of no special importance. Bamstead writes, "a spasmodic stricture is characterized by its short duration." On the other hand, Es-march says it is not only of common occurrence, but may last a long time, and give rise to most severe symptoms. Also, Otis, Berkeley Hill recognize it as reflex and existing under two conditions, first, depending on an anterior stricture, second, on inflammation of the adjacent mucous membrane.

My patient was seventy years of age. First seen three years ago; he had no urinary trouble up to ten years previously. He then began to micturate with difficulty, a slight effort was necessary, and the desire more frequent. These symptoms increased so that in

three years the inconvenience was considerable. The urine was clear and without sediment. The attending physician, after rectal examination, diagnosed hypertrophy of the middle lobe of the prostate. Iodine in some form was given with no benefit. When I first saw him the trouble had increased so much that even when straining the urine would dribble away, five minutes or more being consumed in emptying the bladder. Micturition very frequent, pain at the end of the penis, and a sense of heaviness at the base of the bladder. On rectal examination I was unable to determine the existence of an enlarged prostate. Was there a stricture, and did the bladder empty itself thoroughly? The patient having previously passed as much urine as he could, an English rubber catheter was introduced, but was arrested at apparently the membranous portion of the urethra. A silver catheter, No. 7, was now tried with the same result. A steady pressure being kept up for several minutes, much to my surprise the resistance ceased, and the instrument glided on to the bladder. There was very little urine found, not more than might have been secreted in the interval since micturition. The next day the report was most surprising and gratifying. There was only a slight soreness during urination. The difficulty had entirely disappeared. The stream was full and strong; the water could be retained four to five hours without inconvenience. This state of affairs had persisted up to date, there having been a complete cessation of all symptoms.

The interesting features of this case are the long duration of the trouble, some symptoms simulating graver disease, and their complete relief after one catheterization.

Momentary spasmodic urethral contraction is of common occurrence. It is seen in persons unable to urinate in the presence of others; it is often reflex in origin, as seen after operations on the neighboring parts, or disease of the mucous membrane or bladder may suffice to produce it.

Dr. Otis refers to the last cause as obtaining in many cases where two strictures have been diagnosed, one anterior, the other in the bulbous portion. If the first is divided the second disappears. He considers the second stricture a reflex cramp. This was noticed and explained by Civiale in 1850. Later Verneuil called attention to it, and both he and his pupil, Tolet, reported numerous cases.

The diagnosis and treatment are happily combined in catheterization. The two conditions with which it may be confounded are inflammatory swelling and stricture. The sudden relaxation and easy passage of the instrument, sometimes only possible after anaesthesia, is inconsistent with inflammatory swelling, and the tight grip which a stricture maintains, preventing the easy withdrawal of the instrument, excludes the latter.

Dr. Otis has detailed a series of cases illustrating this; in all of them there had been gonorrhœa, followed by symptoms of stricture, lasting in one case seventeen years. In all the diagnoses of double stricture that had been made the division of the anterior stricture, sometimes so slight as to be overlooked unless tested by the urethrometer, was usually followed by the easy introduction of a large sound into the bladder. What the exciting cause was in my case I am unable to say. There was no suspicion of gonorrhœa. He was not of a nervous temperament. The urine was normal.

In other analogous affections a similar method of

treatment is employed with the best results, as in vaginismus and cramp dependent on fissure of the anus. I am convinced that many cases of dysmenorrhœa are due to spasmodic contraction, and that division of the cervix might be replaced by systematic forcible dilatation. Cystitis in the female seems to be frequently dependent on cramp of the urethra, if not previously for its occurrence, at least secondarily for its continuance. Numerous cures have been effected by forcible dilatation. A writer in the *Lancet* reports between thirty and forty.

The seat of urethral cramp is between the two layers of the deep perineal fascia, or triangular ligament, where lies the complex muscular arrangement which prevents the escape of urine. The sphincter is situated, not at the neck of the bladder, but beyond the prostatic portion, in the so-called *pars muscularis*.

There are one or two points of practical interest in connection with the case. It is not safe to assume the existence of prostatic hypertrophy even with a train of symptoms most suggestive of it. In catheterizing it is well to make continued pressure for some minutes."

Dr. T. B. CURTIS said that the name *urethrismus* was new to him; he thought it eminently suitable, however, to designate long-lasting or permanent spasm of the urethral sphincter or "cut off muscle." The latter, anatomically known as the *compressor urethrae*, is composed of striped muscular fibres, encircling the membranous portion of the canal and situated between the two layers of the triangular ligament. It has long been recognized that these sphincteric muscular fibres, surrounding the deep urethra just in front of the apex of the prostate, at a distance of about six inches from the meatus, were liable, by inopportune and persistent contraction, to oppose occasionally the exit of urine and the entrance of instruments, and thus to cause symptoms of urethral obstruction more or less closely simulating organic stricture.

Micturition, when normally executed, takes place readily, as the result of a desire or call to pass water, the latter originating from an irritation of the exquisitely sensitive mucous membrane lining the neck of the bladder and the prostatic urethra. Any irritation of this mucous surface, whether physiological, pathological, or accidental (*e. g.*, by catheterism), whether by the penetration of urine from within, of injected liquids from without, of instruments or foreign bodies, occasions instantaneously a peculiar sensation which is perceived almost exclusively as a call to urinate, and which, being transmitted centripetally by the sensory nerves to and through the lumbar medulla, serves as a reflex stimulus, motor and inhibitory, to the retaining and evacuating apparatus of the bladder. The effects so produced, under normal conditions, comprise, simultaneously, the inhibitory relaxation of the sphincteric muscular fibres and the active contraction, more or less energetic, of the unstriped muscular fibres contained in the bladder wall, and occasionally also of the abdominal muscles.

This somewhat complicated nervo-muscular mechanism operates to a certain extent automatically, being subject to volitional control only partially, and in a variable degree in different individuals. In some emotional or neurotic subjects the operation of the retaining and evacuating apparatus, involving as it does the orderly consensus of mutually antagonistic sets of muscles, is easily deranged; a form of disordered or ataxic action, which Sir James Paget, in his clinical lecture on Stammering with other Parts than those of Speech,

calls "urinary stammering," may, under certain disturbing influences, then be observed. The speaker had a friend in Paris whose bladder was subject to this sort of stammering, and was so unruly that he could never succeed in passing water except in the familiar privacy of his own bedchamber; in consequence of this infirmity he would sometimes, when far away, have to return home, at great inconvenience, in order to relieve his distended bladder.

In certain pathological conditions of the urinary organs (such as obstructive hypertrophy of the prostate, with retention, complete or only partial; vesical calculus; stricture, narrow or wide; cystitis, however caused), involving as a complication inflammation of the neck of the bladder (cysto-prostatitis), and thereby giving rise to a hyperæsthetic, exalted, and perverted sensibility of the prostatic mucous membrane, the urethral sphincter not only may cease to be subject in any degree to volitional control, but also becomes liable to act automatically in a disorderly manner. Spasmodic action then occurs at the very moment when the physiological inhibitory relaxation is wished for, impatiently expected, and ought to take place; when expulsive efforts are being made, when vesical tenesmus even is being experienced, or when, on the other hand, attempts at catheterism are being made. Many patients who are dependent upon the habitual use of the catheter, are unable, when suffering most severely from vesical repletion and urgent desires to urinate, to relax the sphincter, so as to allow the penetration of the instrument, until the conclusion of a prolonged and painful contest between the evacuating muscles on the one hand and the retaining sphincteric muscle on the other hand. This struggle for the supremacy, at which the patient assists without being able either to abridge it or in any degree to control the opposing forces, sooner or later eventuates in the discomfiture and abdication, so to speak, of the sphincter; a few drops of purulent urine are with difficulty expelled from the prostatic urethra, after which all opposition to the penetration of the catheter ceases.

These disturbances are most common perhaps in persons suffering from urethral stricture; not only in cases of inveterate, narrow, deep-seated, perineal strictures, which every practitioner, however inexperienced and uninformed, is ready to recognize as such; but also, as shown by Verneuil, Guyon, Otis, J. W. White, and many others, in cases of tolerably wide, anterior stricture, of recent development. In such cases the most conspicuous symptom, or perhaps, the only other symptom complained of by the patient besides the urinary stammering and the urethrismus, is an obstinate gleet. Not only acquired strictures of comparatively wide calibre, but even, as abundantly shown by Dr. F. N. Otis, and others, congenital contractions of the meatus, more or less pronounced, and playing the part of strictures, behind which chronic urethritis or gleet has established itself, may be the origin and perpetuating cause of the nervous disturbances which are expressed in the form of chronic urethral spasm.

Until the publication of Dr. Otis's views and experience, in 1876, corroborated by the testimony of Dr. J. W. White, in 1877, it had been almost universally agreed that spasm of the urethral sphincter was always temporary, and that the obstruction so caused was in all cases to be distinguished from that due to organic or permanent stricture by its short duration or by its intermittent character. Dr. Otis's very curious and strik-

ing cases show, however, that a spasmodic contraction possessing almost all the recognized clinical characters of deep-seated, perineal, narrow, organic strictures, including the persistent obstruction caused by the latter, and maintaining a chronic course, may be perpetuated by a chronic irritation of the deep urethra, originating either in slight, that is to say, wide, organic stricture of the anterior part of the urethra, or in contraction, even moderate in degree, acquired or congenital, of the meatus. In 1877 Dr. Otis had published seven very remarkable cases of this kind. In one of these cases, a New York surgeon, over sixty years of age, had been under treatment for deep organic stricture for nearly twenty years; he had at times been able to pass only filiform bougies; false passages had been inflicted; chills and fever had often occurred; there was habitually a high degree of vesical irritation and tenesmus. Notwithstanding all these apparently unequivocal symptoms of confirmed, inveterate, narrow stricture, from which the patient himself expected no relief except from a cutting operation, Dr. Otis, to the amazement and even alarm of the patient, introduced with ease through the canal a 28 (French) steel sound, such being the calibre of the patient's meatus. Meatotomy was performed in presence of several surgeons, among whom were Professor Willard Parker and Dr. Gurdon Buck. After enlargement of the meatus, by incision to 34, such being, according to Dr. Otis's scale of proportion, the normal calibre of the urethra in this case, a full-sized bougie was easily introduced, and subsequently all the distressing symptoms disappeared.

The diagnosis between a symptomatic urethrismus, dependent upon a wide, incipient, anterior contraction of the urethra or upon a narrow meatus, on the one hand, and a deep-seated, narrow, organic stricture, on the other hand, rests mainly, according to the teachings of the most experienced specialists, — such as Otis and Guyon, among others, — upon the results to be obtained by a careful exploration of the anterior part of the urethra, preferably by means of a series of graduated acorn-tipped exploring bougies.

Organic stricture, except in cases of traumatic origin, where a close, cicatricial, transverse contraction situated in the perineal urethra, in the neighborhood of the triangular ligament, is developed in a few weeks after a violent contusion of the perineum, is almost invariably a very remote result of a long-standing gleet, succeeding repeated attacks of gonorrhœa. In such cases a chronic urethritis perpetuates itself behind a narrow meatus or behind a wide anterior stricture; the urethral mucous membrane becomes gradually more and more thickened, inextensible, and contracted; imperfect drainage results, and the canal fails to empty itself completely at each act of micturition; the morbid process creeps slowly backward, and the urethra is progressively narrowed by the retrograde alterations which ensue. After years of continuance, marked by the persistence of gleet, accompanied, perhaps, by more or less functional disturbance of the genito-urinary apparatus, a narrow, deep-seated organic stricture, constituting a permanent obstruction both to the exit of urine and to the entrance of instruments, is the result. But, although here, as in cases of symptomatic urethrismus, the chief point of obstruction is in the deep urethra, the entire canal in front of the narrowest point is also more or less contracted and thickened; and a condition of organic disease exists throughout the anterior urethra which a methodic exploration with acorn-tipped bougies cannot fail to reveal.

DR. CURTIS alluded to a common error of practitioners which consisted in relying upon a digital examination *per rectum* in cases where senile hypertrophy of the prostate was suspected. The size of the prostate *per se* was really of no consequence whatever, unless the retaining and evacuating functions of the bladder were thereby interfered with. The prostatic disease of old men should be called *obstructive hypertrophy* of the prostate, or chronic prostatic obstruction. Unless such obstruction existed, habitually preventing the bladder from emptying itself, and causing complete or partial retention of urine, the disease known as *hypertrophy of the prostate* could not be said to exist. The sole trustworthy diagnostic test for the recognition of this disorder consisted in the introduction of a catheter immediately after full attempts on the part of the patient at complete natural micturition. The detection, by this simple means, of unevacuated urine, "back-water," or "residual urine," afforded conclusive diagnostic evidence of the incurable, chronic malady which the rational signs had led the practitioner to suspect.

DR. H. F. DAXON reported a case of Glanders occurring in a Woman.

It was voted that the meeting on the second Saturday of the month be discontinued.

Recent Literature.

A System of Oral Surgery: Being a Treatise on the Diseases and Surgery of the Mouth, Jaws, and Associate Parts. By JAMES E. GARRETSON, M. D., D. D. S. Illustrated with numerous Steel Plates and Wood-Cuts. Third Edition, thoroughly revised, with Additions. Philadelphia: J. B. Lippincott & Co. 1881.

An extended review of this admirable work is unnecessary, it having been for years accepted as a standard text-book in the dental schools. The author's eminent position giving great weight to his opinions, it is worth while, however, to call attention to some points about which there may be a difference of opinion. Although professing to be a work on surgery, space is given to the anatomy of the teeth and surrounding parts. Perhaps the reason for this is to be found in the needs of the dental student, who in most of the dental schools is obliged to study surgery as soon as anatomy.

When a progressive medical education is recognized as a necessity for every one who practices upon the mouth, then students will not attempt the study of surgery till they have mastered anatomy, and the text-books can be confined each to its special province.

In the work under consideration the advantage which would result is apparent, as slight errors are to be found in the anatomical descriptions. For example, on page 31, the author, in describing the molars, says "these teeth have crowns of cuboid shape, are four cusped." Any one, however, may see by examining a number of skulls that the inferior first permanent molars have five cusps,—two internal, two external, one externo-posterior. Nor are their crowns cuboidal in shape. In passing to the treatment of decay we find partial excavation recommended for cavities extending under the gum. The cavity is then to be packed with cotton, which by the next day will have pushed the gum away. Such treatment would give unnecessary pain, for when living dental fibrils are cut an inflammation results, making the tooth acutely sensitive for

several days. On page 61 the author justly says, "mechanically viewed the coffer-dam is undeniably perfect, surgically considered no means employed in dental art is more abused." Up to the present time the coffer-dam has done more harm than good, because it has made long, exhausting operations possible and popular.

On page 66, in directing attention to oxychloride of zinc as a lining for cavities to be filled with amalgam, the disintegration of all oxychlorides, which takes place in the mouth, seems to have been forgotten. A cavity so filled would in most cases soon show a narrow fissure between the amalgam and the walls of the tooth, out of which the oxychloride had crumbled. Under the head of oxychlorides and zinc phosphates nothing is said to indicate the temporary nature of these fillings. In the enumeration of the methods of treating decay in teeth vitrine fillings are not mentioned, though they are useful where appearance is of consequence. More explicit directions should be given for drying the cavity after excavating decay in a tooth. The mechanical means should be followed by the use of warm absolute alcohol; the semi-desiccated tissue should then be filled with wood creosote.

We notice with pleasure in the chapter on artificial crowns that Dr. Bourvill's ingenious method is fully illustrated. Chapter VI. is devoted to irregularities. The author says the period from twelve to seventeen years is to be selected for treatment. This is certainly the general opinion, yet when the incisors come far out of place they should be regulated soon after eruption. For the cells of bone surrounding the teeth are at this time comparatively large, so there is less absorption of bone, and consequently less irritation in moving the teeth than at a later period when the sockets are smaller and more dense. Besides, if we wait till most of the teeth are in place we shall often be obliged to regulate teeth which have come out of place on account of previous unreduced mal-eruptions. Regulating at this early age is attended with little inconvenience, even to a sensitive child, if we use proper apparatus. In Chapter X.—Prosthetic Dentistry—the reader is surprised to find no mention of Godiva modeling composition. Nor does the author speak of taking impressions of natural teeth as an aid in making artificial ones, though a series of such models is of great value. The chapter on associated lesions of the first dentition is full and clear. Lancing the gums is advocated to relieve irritation from erupting teeth. On page 296—Anomalies of Second Dentition—we find this passage: "The permanent set is to comprise in number sixteen, and each tooth quite as large again as its predecessor." This is untrue, particularly of the premolars, the successors of the temporary molars. Nor can we accept as final the statement, "in proportion to the number of deciduous teeth removed prematurely will be the curtailment in size of the arch," resulting in "approximal caries, periosteal troubles, trismus, odontocoele, necrosis, and the violent inflammations attendant on the development of the dentes sapientiae." The truth is we may take out almost all the temporary teeth except the canines without having the permanent set come irregularly.

Beside, permanent teeth may be killed by allowing devitalized, deciduous teeth to remain.¹ In this and the succeeding chapters the author is evidently more at home than in the mechanical operations about the

¹ Boston Medical and Surgical Journal, vol. xcvi., pp. 393, 394.

teeth, the work consequently increases in interest. We should advise orists to read this portion of the work carefully, for all are too apt to neglect to treat caries of the teeth except by filling. In Chapter XVIII., Diseases of the Teeth, attention is called to the importance of the late eruption of the deciduous teeth as an aid in the diagnosis of rickets, which, it is stated, may be present without bone symptoms. In enumerating the causes of dental caries this passage occurs: "The surface most liable to suffer from caries is the approximal. This in many instances finds explanation in the constant abrasion here going on as the result of motion produced by the act of mastication, the enamel being literally worn or cracked away." One may be allowed to differ here, for if constant abrasion be present polished surfaces will result, and such surfaces will not be likely to decay. Rare indeed are cases where such abrasion will crack off the enamel. Nor can we accept this statement without question: "In other cases the dentine becomes deprived of its protecting covering as the result of lateral pressure, such pressure being increased with the development of each tooth."

In looking at the work as a whole the author's width of view is clearly apparent, his grasp of the more purely medical and surgical portion of his subject is firm, but in the mechanical operations about the teeth he is less at home. It is therefore to be regretted that the work was not confined within narrower limits, as much of the subject matter could be better studied in works on anatomy, operative and mechanical dentistry.

ROLLINS.

Anatomical Plates, arranged as a companion volume for The Essentials of Anatomy, and for all works on descriptive anatomy, comprising four hundred and thirty-nine designs on steel by Professor J. N. Masse, of Paris, and numerous diagrammatic cuts selected or designed by the editor, together with explanatory letter-press. Edited by AMBROSE L. RANNEY, A. M., M. D. New York: G. P. Putnam's Sons. 1881.

The Essentials of Anatomy, by Professors Darling and Ranney, which appeared rather more than a year ago, is very happily completed by this small, portable, and very satisfactory atlas. The plates, to be sure, represent descriptive anatomy; that is, muscles, vessels, nerves, etc., are treated separately; but, though rather unequal in execution, they are very good of their kind. Some of the diagrams please us very much.

Medical Heresies: Historically Considered. A Series of Critical Essays on the Origin and Evolution of Sectarian Medicine, Embracing a Special Sketch and Review of Homoeopathy, Past and Present. By GONZALVO C. SMYTHE, M. D., Professor of the Practice of Medicine, Central College of Physicians and Surgeons, Indianapolis. Philadelphia: Presley Blakiston. 1880. Pp. 228.

The author very modestly prefaces his book with the remark that "every person who proposes to inflict a new book upon the profession should be able to give a good reason therefor." His object is to present in a condensed form the history of the "rise, progress, and fall of the various schools, sects, or systems of medicine from the earliest historical period to the present." The first part of the book does not differ much in general

scope and plan from many of the condensed text-books in general history that have appeared in the last few years, and might very properly be called Outlines of Medical History. The second and larger part is appropriated to homoeopathy. The author's second, and, judging from the space devoted to it, his chief reason for writing lay in his desire to disseminate information in regard to this subject which he believes to be much needed. It is his aim to present the views of the believers in the dogma fairly, and with this object in view he quotes liberally from the Organon of Hahnemann and the writings of his disciples. The present status of homoeopathy is shown by extracts from society proceedings and current periodical literature which illustrate the various schisms and shades of belief which divide the sect. Few practitioners have the time or opportunity to investigate the claims of the present generation of homoeopathic practitioners; to all who desire to be informed upon the subject Dr. Smythe's book will prove welcome.

— St. Paul, Minnesota, was selected as the place for the next annual meeting of the American Medical Association, and Dr. Stone was appointed chairman of the local Committee of Arrangements.

The following officers were elected for the ensuing year:—

President, Dr. T. J. Woodward, U. S. A.

Vice-Presidents, Drs. P. O. Harper, Arkansas; L. Conner, Michigan; Eugene Gressom, North Carolina; and Hunter McGuire, Virginia.

Secretary, Dr. Wm. B. Atkinson, Pennsylvania.

Treasurer, Dr. R. J. Duglison, Pennsylvania.

Librarian, Dr. Wm. Lee, Washington.

Dr. Joseph J. Woodward, the newly elected president, is from Washington, D. C. He was born in Philadelphia in 1832. He was educated at the Philadelphia Central High School, from which he received the degree of A. B. in 1850, and that of A. M. in 1855. After receiving his first degree he began the study of medicine and graduated from the University of Pennsylvania in the spring of 1853. For some time thereafter he practiced his profession in Philadelphia, acting during that time as examiner and teacher upon microscopical and pathological anatomy. He entered the army and rose rapidly, and is now the chief-assistant in the surgeon-general's bureau at Washington, with the rank of lieutenant-colonel. He is the medical editor the Medical and Surgical History of the Rebellion. His professional labors have been of distinguished character, none more so than his comprehensive series of experiments in microscopic philography, by which the profession has been placed in possession of records of the highest value and usefulness. Dr. Woodward is the author of many valuable works, all of which have been most favorably received by the medical profession. He was a member during his residence in Philadelphia of the Philadelphia County Medical Society; is a member of the American Medical Association, and was its second vice-president in 1875; was a delegate to the International Medical Congress, at Philadelphia, in 1876, and is a member of the Medical Association of the District of Columbia. There is no doubt but what he will make a most efficient officer.

The election of Dr. Woodward to the presidency is all the more complimentary, as he was not present, and the high honor was entirely unought and unexpected. — *Virginia Medical Monthly*.

Medical and Surgical Journal.

THURSDAY, MAY 12, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

MANAGEMENT OF AMERICAN PUBLIC INSTITUTIONS SEEN THROUGH ENGLISH GLASSES.

IN the April number for 1881 of the *English Journal of Mental Science* there is, among other good things, a highly edifying editorial entitled, *The Influence of Democratic Feeling in America on the Management of Public Institutions*. Public institutions here refers particularly to insane hospitals, the writer having, evidently, very recently, made a visit to a number of these. Much clearness of perception and sharp penetration are shown in this article, as well as an honest desire to tell the truth without shrinking, and we therefore propose to give some extracts, criticising such of them as we believe are not quite correct, believing, as we do, that there can be no harm in occasionally hearing what our friends have to say of us behind our backs.

The writer begins by saying that "The mode in which the political constitution of a country affects its social arrangements has always been an interesting subject of study. But there has not been nearly so much attention given to the way in which the politics of a country affect the origin, government, and administration of its public institutions. . . . America, with its distinct States and state rights, its democratic constitution, its intense and jealous parochialism, as regards local affairs, is an admirable field in which to study this branch of sociology. Indeed, its public institutions cannot be understood except we take into account the political constitution of the society in which they originated. One might as well criticise a landscape without reference to the sunshine and the geology of the country, as speak of the colleges or asylums of America without taking into account its state legislatures, its county government, and its never-ceasing legislation. An educated democracy is easily moved, is very much given to spasmodic bursts of charity, and is always creating public institutions of some sort, while it is intensely jealous of them, and often very unjust to them." We will grant that public institutions are easily created in this country, but we have not observed the jealousy of them of which the writer speaks. On the contrary, unless some instance of gross mismanagement has been, perhaps accidentally, unearthed, they pursue the even tenor of their way, a source of pride and satisfaction to the people, who are singularly ingenuous in the confidence they repose in their managers. We are a people sudden and quick in action when aroused, but put up for

an astonishingly long time with public abuses. We are jealous of certain corporations, it may be said with truth, and are constantly legislating to modify and suspend their powers, but our indignation has been awakened by their corrupt practices in past years, which have made us suspicious of them.

The writer continues, "There is no finer field for small autocrats, too, than in an absolute democracy. Conservatism of a certain kind is never so secure against change as when it has universal suffrage to back it. Individualism is more marked in America to-day than it is in Great Britain, but it takes different directions. Plenty of people are to be met with in America who declare that Washington was an old fool, that the present republic there is a mistake, that universal suffrage is a delusion, and that they would be better off under an emperor." We are surprised that the writer should have fallen in with such a number of anti-Washingtonians, for in our own experience the persons who would express themselves in the above words are much more rare. It is a part of our education, of our very inmost soul's belief, to reverence Washington, and though his personal influence is no longer felt, as all men are dead who came into contact with him, his name is held so high that it is above the reach of our national irreverence for men and things.

To continue with our extracts, "If the head of a public institution there is strong and bold enough, he may administer its affairs further off the beaten track than could be done in Europe. But, on the other hand, all the average and weak administrators dare not for their lives turn to the right or the left of the path which the public opinion of the place and time prescribe." The last sentence is capable of a considerable modification, for the average and weak administrators are often controlled by the "boss," or other persons, whose tool they are, and not by public opinion. Take, for instance, the recent street-cleaning difficulty in New York. There was a case in which public opinion said, unanimously, the streets must be cleaned, but a few politicians saying otherwise, the weak administrators were sustained, and public opinion was ignored. So we could cite other instances where weak and corrupt administrators are continued in office, where the public cry for their removal, and the newspapers are loud in their denunciations, but the powerful arm of one or more politicians shields them from the storm.

"In America there is a far greater social equality between the governors of asylums and the physicians than there is in the English or Irish counties. There is no such thing there as an asylum physician who does not mix in the same society as his Board of Governors. This is certainly more conducive to his *amour propre* than the state of matters in some counties of England, and it gives him a more direct power and authority with them. But for that very reason he needs to be at all times educating his masters in some way, who are often changing and often personally jealous of his superior knowledge of his own subject." We ourselves have not happened to come

across many such instances of jealousy, but we have often been struck with the spirit of admiration which seems to fill the breast of many trustees for their superintendent. They show him off like a prize baby; they hold him up to the light, exhibit his charms, and ery in an enraptured chorus, "See what a prodigy we have! See how he manages the kitchen, the garden, and the sewing-room! So young, and yet so wise!" Turn to the statements of trustees in their annual reports for easy verification of these assertions.

In the next sentence the writer says, "This accounts for the tone of rather strained philanthropic zeal that pervades many American asylum reports. The expression of religious sentiments in reports, too, is thus accounted for, conforming to the remaining shadows of the former Puritanical modes of feeling prevalent in many portions of the country." We have ourselves frequently occasion to deplore the melancholy religious platitudes which are gracefully sprinkled through the pages of insane hospital reports, and we explain this not by any relationship between trustee and superintendent, but partly by our inherited religious superstitions, as asserted by the writer, but much more from a lack of anything better to say. When the science of insanity is more thoroughly understood and more time devoted to its study in asylums, as is the case abroad, we shall find scientific observations replacing religious truisms and antiquated generalizations.

"The direct dependence on local public opinion gives a sense of insecurity of tenure, and produces a faint-heartedness of management that we think often affects the efficiency of institutions. In reality, there is far more conservatism in American asylums than we have here. There is far more diversity, too, comparing one asylum with another, there being no central authority to produce uniformity and convey the precedent of what is done in one place to another.

"There is, thus, in America a more direct appeal to the public, as to the philanthropic character and aims of hospitals for the insane than here and less of the settled-down official character about them. The pulse of that human charity that originally started such institutions has to be more constantly felt and relied on than here. Therefore the external and visible matters need to be more attended to. The imagination of the public requires to be more directly appealed to. In no other way can we account for the magnificent costly architecture, the grand porticoes, the gorgeous entrance halls, and the luxuriously furnished reception rooms in some of the new asylums in some of the Northern States. A strong man at the head of an institution in America, who is reckoned fairly honest, who can do electioneering, so far as it concerns himself, who can make a good public appearance, and who has a good social position, is master of the situation. He can do anything, and get anything, and make his governors believe anything; but he can't rest on his oars. He must always be on the alert."

The element of philanthropy is certainly a prominent one in our republican form of government. All men being born free and politically equal, we feel

obliged, as a matter of principle, to treat every unfortunate as if he were our own dear brother, and consequently in providing for our insane we give our paupers too sumptuous surroundings, and the better class of impoverished persons, grown poor from their disease, surroundings hardly good enough. In time, no doubt, social lines will be more sharply defined and the different social classes of the insane more separated.

The "costly architecture," the "grand porticoes," etc., we think are not owing to the necessity of appealing to the public imagination, as the public common sense strongly shows its displeasure at these stage effects, but grows rather out of an accidental combination of circumstances. A new hospital is to be built, a building commission is appointed by the governor. They consult an architect ignorant of the needs of the insane, but anxious to introduce innumerable cornices and other architectural ornamentation inside and out. The commissioners, in all probability equally ignorant of both insanity and architecture, readily yield to his propositions, perhaps calling to their aid some hospital superintendent who cannot be assumed to know much of architecture. The process of building is more or less hap-hazard at its inception, and when too late the State finds itself burdened with an elephant built after the crude designs of the building commissioners, the architect, and the superintendent. We cannot deny that the quarters of the patients are too uniform, while the officers' quarters are unnecessarily sumptuous, but would ascribe this to mistaken ideas of the treatment of the insane rather than to narrow self-seeking for personal comfort.

The quotations made above nearly finish this pithy article, which certainly contains suggestions enough to set us all a-thinking. We regret that want of space prevents the insertion of the closing paragraph.

TRAVERS VERSUS BOARDMAN. THE SEQUEL.

On February 14th of the current year we spoke at some length of this case, and expressed the hope that it might speedily be brought a second time before the court, and terminate in accordance with justice. We again call attention to the case to record the result of the second trial.

The plaintiff was duly put upon the stand as her own chief witness, and again told her story; before the cross-examination was concluded, or had even advanced beyond preliminaries to the main facts at issue, her lawyer abandoned the case, stating that he had been grossly deceived by his client. The judge ordered a verdict to be recorded for the defendant.

The case proceeded far enough to show the witness to be entirely untrustworthy in all minor matters. She claimed to have been born thirty-one years ago, and had rearranged the other dates of her life — her marriage and her husband's death — to support that claim. Cross-examination showed her testimony to be false on these points, and the defense was ready to show that she was over fifty years of age, and that

consequently the cessation of menstruation, which she alleged had followed her treatment, was but the natural result of years. Placing her husband's death later than the actual occurrence, she denied her own signature affixed to papers which were produced in court connected with the administration of his estate, and, finally, denied her signature affixed to a document pertaining to the present trial, and executed before her own lawyer.

To Dr. Boardman we extend our congratulations. No one who knew anything of the case could doubt what the verdict would be if it were once fairly presented, but the mental disquietude inseparable from such persecution is by no means slight.

To the guileless victim of his artful client's wiles, the plaintiff's legal adviser, we extend the sympathy due to a much-wronged man. He, too, has suffered. For his outraged feelings, for his betrayed confidence, we offer the only consolation in our power, to wit, the gratifying reflection that less harm has been caused to innocent individuals and to society at large than might at one time have been anticipated.

There is one poor consolation to be found in the matter. Probably the profession in the city was never so thoroughly canvassed for a witness as in this case, but, notwithstanding the supposed readiness with which medical men can be found to testify on any side of any case, no one with the slightest claim to professional standing was ready to support the plaintiff's allegations; legal talent, however, proved in this instance less scrupulous.

There is also a lesson to be learned from the double trial. Truth needs to be well supported when she appears before a jury, and no man can, in a medico-legal case, so far rely upon the simple justice of his cause as to safely leave the search for witnesses until the very morning of the trial.

MEDICAL NOTES.

—The somewhat full report of the meeting of the American Medical Association at Richmond, which we publish, has crowded out our usual material from the second part of this issue of the *JOURNAL*.

—The bill to prevent incompetent persons from doing business as apothecaries was rejected in the Massachusetts House of Representatives by a vote eighty-eight yeas to ninety-six nays.

—The sparks continue to fly. Two further cases of small-pox have been reported to the Board of Health. One was infected by a case already mentioned in the *JOURNAL*. The second came from New York to a boarding-house in the Brighton district. Measles was already present in the house, and the small-pox eruption, on its appearance, was considered of the same nature, and no physician was called for two days.

—Prof. L. McLane Tiffany has been elected professor of surgery in the University of Maryland. He succeeds Prof. Christopher Johnston, who has been made emeritus professor.

Miscellany.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.¹

The American Medical Association began its thirty-second annual session at eleven o'clock A. M., Tuesday, May 3d, at Mozart Hall, at Richmond, Va. About five hundred members were on hand.

FIRST DAY'S PROCEEDINGS. GENERAL SESSION.

The Association was called to order by Dr. Frank Cunningham, chairman of the local committee of arrangements.

Dr. H. D. Holton, of Vermont, vice-president of the Association, occupied the chair, with Dr. William B. Atkinson, of Philadelphia, Pa., acting as secretary.

The exercises opened with prayer by the Right Rev. Bishop J. J. Keane.

Dr. Cunningham then, in brief and appropriate language, introduced Governor F. W. M. Holliday, who had kindly consented to deliver the address of welcome.

The address of Governor Holliday was cordial and appropriate, and his remarks were loudly applauded.

The secretary next called the roll of members who had registered.

A motion to dispense with the calling of the roll was laid on the table.

The names read were, on motion of Dr. Toner, all confirmed in their membership.

Dr. Cunningham, from the committee of arrangements, read to the Association invitations from the Commercial, Richmond, and Westmoreland Clubs tendering the hospitalities of these clubs to the members during the session of the Association. The invitations were accepted, and, on motion of Dr. D. J. Roberts, the thanks of the Association tendered for the same.

The president, Dr. John T. Hodgen, of St. Louis, then delivered the annual address. The subject selected was the Recent Exceptional Strides in the Progress of Medical Science, both in the Direction of Extending the Domain and Perfecting the Methods of Operative Surgery.

He divided surgeons into those seeking to perform every practicable operation, and those avoiding operations whenever it is possible.

The former include the bold, the enterprising, the ambitious, and the reckless of our profession. The other, the timid, the conservative, the cautious, and the procrastinating. The former class is largely made up of young men, enthusiastic and full of inspiration, caught from professors, whose task is to make the way clear and easy, students of the current medical literature, which teems with new suggestions and is crowded with reports of remarkable cases and wonderful operations, generally ending, or reported as ending, happily to the patient, and to the great credit of the reporter.

Simon excises a kidney, turns an aberrant ureter into the rectum, touches, through the natural passages, a stone in the kidney, and immediately hundreds of ambitious surgeons are seeking kidneys to excise, ureters to turn, and renal calculi to touch. Battey removes an ovary for the relief of an obscure nervous disorder, and forthwith ovaries are removed for almost every imaginable nervous disorder. Billroth cuts out

¹ Our reporter wishes to acknowledge his indebtedness to the daily issue of the *Virginia Medical Monthly*.

a cancerous larynx or a diseased pylorus, and at once a demand springs up for similar cases, and the daring operations are repeated in all the four quarters of the globe.

The second class is recruited largely from the first, and often only after many lessons of bitter disappointment drawn from the experience of many and grave disasters.

Dr. Hodgen then illustrated the practice of operating by blindly following the dicta of authority by two procedures resorted to by gynecologists with great frequency during the last twelve or fifteen years, namely, the division of the cervix uteri for flexures, and the methods adopted for the cure of lacerations of the cervix uteri.

He touched upon the great danger of specialties being based upon too narrow a foundation, and said: In the best sense a specialist is a physician and something more, in the worst, he is something else and something less than a physician.

He thought that, captivated as men were by the rapid progress made of late years in the precision and perfection of regional surgery, they were in danger of overlooking the general influences which are ever present to modify and control the results of local injuries. After referring to a number of these conditions, the speaker concluded his address with the following remarks:—

Besides want of space, another reason for the omission of reference to other conditions which may demand or forbid a resort to the knife, is our want of exact knowledge. Especially is this true of those constitutional conditions we term diathesis. Using the word in its broadest sense, diathesis is any condition varying from the normal standard which disposes to the development of disease in the presence of trivial exciting causes. Other conditions which we habitually include under diathesis are themselves diseases—such, for instance, are scurvy, the scrofulous habit, tuberculosis, and syphilis. A diathesis may be transient or permanent, retrogressive or progressive; it may be so marked in its manifestations as to force its recognition upon even the most careless observer, or it may be so obscure as to elude the most painstaking scrutiny; and yet it may respond immediately and disastrously to an injury. In acknowledging our ignorance regarding the precise nature of such variations from the normal standard as we believe must exist in diseases like scurvy, scrofula, tuberculosis, etc., we recognize the existence of wide uncultivated fields, rich, no doubt, in promise to future investigators. A more perfect animal chemistry, a more thorough histology, and a deeper research into the possibilities of pathological change, will doubtless throw many a ray of light into regions where the darkness is now too dense for our vision to penetrate. To these fields coming generations of physicians will surely be attracted, in the faith that as man advances in knowledge, and approaches somewhat nearer to the comprehension of the perfect wisdom which designed the wonderful physical organism, through which he is brought into relation with the world around him, he will be enabled to solve more and more of the difficult problems which now perplex and baffle us, and will gradually raise medicine to a position more nearly akin to that now accorded to the exacter sciences.

Dr. Joseph H. Warren, of Boston, chairman of Committee of Foreign Delegates Abroad, then presented his report. The reading of the report was deferred, and it was referred to the Publication Committee.

SECTIONS.

I. SURGERY AND ANATOMY.—Chairman, Dr. Hunter McGuire, of Virginia; secretary, Dr. Duncan Eve, of Tennessee. Dr. J. H. Warren, of Boston, opened the work of the section by exhibiting a collection of instruments devised by himself, which have been previously described in the columns of the *JOURNAL*. In regard to some of these instruments, both Dr. Sayre and Dr. Gouley, of New York, thought that they possessed nothing—not even simplicity—to recommend them.

Dr. Burgett reported an interesting case of ulceration of the appendix vermiformis, with remarks upon abdominal section in cases of perforation of the bowel. The writer took grounds strongly in favor of operative interference, and based his opinions on experience in many cases. Dr. Burgett advocated early operative interference in inflammatory affections around the cæcum.

Dr. James E. Reeves, of Wheeling, West Va., presented for Dr. B. W. Allen, of Wheeling, a report of a case of pyonephrosis, exhibiting a nephritic calculus weighing 480 grains. The case was that of a widow, age, fifty five years. Her general appearance was that of a great sufferer. She was sallow, emaciated, asthmatic, and constipated. Her bad health dated from her menopause. On examination a large tumor was found extending from the right hypochondrium to the left and pelvis. Fluctuation was marked. Aspiration evacuated eighteen pounds of sero-purulent matter, and this was followed by immediate relief. It was now found that the tumor had no connection with the liver, and the history of the case forbade the idea of its being ovarian. The benefit from the operation was only temporary and death resulted. An autopsy showed a tumor extending from the under surface of the liver with which it was in contact but not adherent, downward into the cavity of the pelvis. The lower end of the ileum ran across the tumor to the ileo-cæcal valve, producing a constriction noticeable before death. The sac was fifteen inches in length, twelve inches wide, and six through. It contained ten pounds of purulent fluid, and was found to be the remains of the left kidney. An enormous renal concretion was found imbedded in the sac, together with smaller ones, weighing 416 grains. At no time were there symptoms of uræmic poison, and the other abdominal organs were healthy.

[A special and full report of Section II. for The Diseases of Children will appear in our next issue.]

III. ORTHAEOLOGY, OTOLOGY, AND LARYNGOLOGY. Chairman, Dr. D. S. Reynolds, of Kentucky; Secretary, Dr. S. M. Burnett, District of Columbia.

A paper was read by Dr. G. T. Stephens on the Perimeter, invented by himself for measuring the field of vision. Dr. Stephens described the instrument closely, remarking that most of the instruments hitherto used are very large, weighing a good many pounds, and consequently inconvenient for using. His instrument removes some of the difficulties. The gentlemen present were invited to examine the instrument.

Dr. W. C. Jarvis next addressed the meeting on the subject of Nasal Catarrh with Hypertrophy. He remarked that the persistence of the disease is due to hypertrophy of tissue. This must be removed, and instruments are necessary to effect this result. The cæraseur is the same instrument described in the *Medical Record*, April, 1881. The wire used is very fine, but exceedingly strong, and made of the best steel. The

transfixion needles are provided with metal handles, and are made of various sizes. The simpler forms of hypertrophies can be removed with the *cérasseur* alone, but sessile growths require both. Dr. Jarvis stated that all degrees of hypertrophy can be removed by means of these instruments. In one patient who had not breathed through the nose for fifteen years, and in one who had never breathed at all through the nostrils, the relief was almost immediate. All kinds of nasal growths can be reached by means of the instruments, and there is no longer any use of resorting to caustics, cutting, and the galvano-cautery.

Dr. Joseph A. White said that he had used the instrument mentioned by Dr. Jarvis, and had obtained excellent results. In one case in which the hearing was only two fiftieths, the result was such as to produce perfect hearing in one side, and partial hearing on the other side, where organic trouble was added.

Dr. Daly said the instrument was a very useful one. In his experience deafness of greater or less degree had often been relieved by removal of nasal growths, and that, too, without treating the deafness at all.

Dr. Chisolm read a paper on the treatment of Conical Cornea. He said that it is a pertinent question how to get the projection back. Suggestions had been made of cutting out a piece of the cornea and bringing the surfaces together. After reading a French article on puncture of the cornea with a needle heated to redness, he determined to put it into practice. A case of exophthalmic goitre with a complication of eye troubles was selected; objects could not be distinguished one foot off. No anæsthetic was given and the needle was thrust suddenly through the cornea. The anterior chamber was immediately emptied; no pain was felt; and atropia and cold water were used. There was no inflammatory action. As soon as the eyes were opened the patient read at six feet. The same operation was used on the right eye, and eight months afterwards the cornea was perceptibly flattened — sufficiently so as to admit of an iridectomy.

Dr. Little said that he had assisted Dr. Noyes, of New York, in a case of conical cornea, where tapping was resorted to. The result was highly satisfactory.

IV. PRACTICE OF MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY. — Met at Mozart Hall at 3 P. M. Dr. Pepper being absent, Dr. J. A. Oesterlony, of Louisville, was called to the chair; Dr. T. A. Ashby, of Baltimore, Secretary.

Dr. W. C. Wile, of Sandy Hook, Conn., read a paper upon Blood-Letting as a Therapeutic Measure in Pneumonia. He said that it was with great hesitation that he approached such a subject, but that, in the light of his past experience, he felt it to be his duty to do so. He could not, in the limited time at his disposal, say anything in regard to the etiology or diagnosis of pneumonia, but should confine his remarks to the consideration of a therapeutic measure. He then proceeded to say that, while he knew he was treading upon almost forbidden ground, and that he would meet with great opposition from the profession at large, he felt compelled to urge the importance of the free use of the lancet in pneumonia. He cited a typical case of what he called "acute catarrhal pneumonia," in which he had recommended the abstraction of blood in the first stage, but in which, owing to the opposition of the family, he had been unable to carry out the practice he recommended until the disease had advanced to the second stage, but even then with the most marked and im-

mediate favorable results. He entered very fully into the details of this case, as it was one of a class which had proved peculiarly fatal in Connecticut, under any treatment he had adopted; and reported a series of twelve other similar consecutive cases, with like favorable results.

Dr. Pepper having arrived at this moment, assumed the chair, and called upon Dr. Gross to open the discussion. Dr. Gross said he should prefer to hear some other gentleman first.

Dr. John J. Lynch, of Baltimore, remarked that he thought, from Dr. Wile's description of his cases, that he had made a mistake in diagnosis, as they were evidently "croupous" and not "catarrhal" pneumonia. The doctor was also probably mistaken in attributing the rapid recovery of his cases to the bleeding, because croupous pneumonia most frequently ends in from two to eight days by sudden crisis, and Dr. W.'s cases would probably have recovered just as soon without the bleeding. Dr. L. admitted that for rapidly extending collateral hyperemia in pneumonia bleeding might be necessary, and was most efficient, but this was from the merely mechanical effect of the remedy, and in no sense curative. The disease would run its course afterwards in spite of the bleeding.

He hoped he would never see the day when the profession returned to the sanguinary method of treating pneumonia less than half a century ago, when the average mortality was more than twenty-five per cent., while by the modern, purely rational method, it was, in uncomplicated cases, not more than four or five per cent.

Dr. Whittaker, of Cincinnati, said that he thought too earnest protest could not be made against this revival of venesection at this late period in the history of science. Pneumonia is now known to be a general disease with a local expression in the lungs, just as typhoid fever is a general disease with a local expression in the intestines. There could be no justification of venesection in pneumonia, except upon the theory of a local inflammation. That pneumonia is, however, not a simple local inflammation is proven by the fact that it differs in its temporal and spatial relations with local inflammations, like bronchitis, and that the local and general symptoms do not correspond in severity. The local signs may be slight, and the constitutional severe, and *vice versa*, just as in typhoid fever or any of the exanthemata. Pneumonia prevails at all times and places, and occurs at all ages of life like the various infectious diseases, and modern pathology has put pneumonia in the category of the acute infections. It would be impossible, therefore, to do anything but harm by the letting of blood at any stage of the disease. How could the letting of blood clear up a consolidated lung? The essayist has, evidently, mistaken the crisis for a cure. The crisis in pneumonia may occur at any time between the fifth and eighth days, and often as early as the third, and neither blood-letting nor any other treatment could possibly cut it short. As for *veratrum viride*, that dangerous cardiac sedative to which the speaker had alluded, it could do nothing but harm. What advantage is there in checking the force and frequency of the heart, when this increase in force and frequency is only compensatory, and is to be favored rather than checked. Pneumonia is due to a poison entering the blood and affecting the whole body, and no amount of blood-letting could let it out, any more than we can drain out the impurities of a stream with a bucket. Our illustrious professor of surgery — may the lustre of his name never

grow less — may succeed by the force of his genius in restoring venesection, the lost art as he calls it, to a place in the domain of surgery, but in internal medicine it is hopelessly and irretrievably lost.

Dr. N. S. Davis, of Chicago, said that he had practiced medicine for nearly half a century, and that for fifteen years he had practiced venesection after the regular sanguinary method, and that he must say that he had found the best results from blood-letting in pneumonia, when discriminately employed.

Dr. Oeterson, of Louisville, Ky., said that he did not wish to discuss the general subject of pneumonia, but to offer some remarks in analysis and friendly criticism of Dr. Wile's paper. In the first place, he did not deny that cases are occasionally met with in which blood-letting is indicated and will prove beneficial in relieving venous congestion, but he did not think Dr. Wile's cases sufficiently numerous to establish a law, nor were they reported with sufficient care to make them available.

The first case, which the Doctor designated as *catarrhal pneumonia*, was evidently *croupous pneumonia*. Of the other cases he gave no account of the physical signs, and so had left the Society in doubt as to the diagnosis.

The first stage of the disease was the period during which Dr. Wile would have us bleed, because this was the stage of engorgement; but that he (Dr. O.) claimed that even at this period exudation had already occurred, as shown by the physical signs, dullness, absence of vesicular murmur and the presence of fine crepitant *râles*. Bleeding will not return this exudation to the vessels; this can only be accomplished by a vital process. The mortality in Dr. W.'s cases was 1 in 13 — far greater than that resulting from the plan of *promoting the natural progress of the disease and supporting the strength of the patient*. The duration of his cases was not less but greater than our knowledge of the natural history of the disease shows to be the rule.

In conclusion, he must insist that the writer had not proved his proposition, namely, that pneumonia is a very fatal disease, nor that the mortality or duration of the disease have been diminished by venesection. On the contrary, it seems to be a well-established fact that pneumonia is a self-limited disease. The blood-letting plan of treatment used to give a mortality of 1 in 5. The purely expectant plan, 1 in 13. The plans he had here recommended gave, in Bennett's hands, a mortality of 1 in 36.

Dr. J. H. Claiborne, of Virginia, said that he did not think we could fail to go astray if we followed the teaching of the gentlemen who always recommended bleeding, nor could we fail to go astray if we believe those who tell us never to bleed. The middle course was safest, and we should be guided more by experience than by theory. There was no one method of treatment applicable to all varieties of pneumonia.

Dr. Post, N. Y., said that in his opinion no dependence could be placed in statistics, as they were drawn from a class of patients found in hospitals, who had been badly clothed and badly housed and fed all their lives, and such statistics were not reliable guides. We must be guided solely by experience. He could not sympathize with the gentleman who expressed the opinion that the lancet could no longer be used in medicine, for he believed that when properly and discriminately used, recovery was more rapid after bleeding.

Dr. Coleman, of Vermont, said that theoretically he believed in the lancet in a certain class of cases, but that in practice he did not meet with that class of cases where the blood was being forced into the lungs so rapidly as to produce strangulation, as he was not called in time to see them in that condition.

Dr. Quimby, of Jersey City, said that in all acute inflammatory cases where he used stimulants he lost his patients. Under a modified treatment he had lost not a patient. All cases where he had used the lancet he had done so on first or second day. He thought we did not often see these typical cases in the very first stages. We can't treat patients as if they were machines. He advocated the free use of the lancet, when properly and timely used.

Dr. Whitney, of New York, said that when he first commenced practice, he had felt it to be his duty to bleed all cases of pneumonia, since then he had to a great extent abandoned the use of the lancet. But that he thought the mortality had never been so great before as since the abandonment of venesection. He thought we did not bleed half enough.

Dr. Jackson, of Virginia, thought it objectionable to speak of blood-letting as a treatment of pneumonia — we ought to speak of it as an adjuvant or auxiliary. It was wrong to let it go abroad among the younger men that we had either advised against or for blood-letting.

Dr. S. D. Gross belonged, he said, to the younger members of the profession. He had listened with deep interest to the remarks made here. Pneumonia was an inflammatory affection, and the lancet, in such affections, was applicable in young, robust, and healthy subjects. Bleeding was not applicable in *all* stages of pneumonia, but only in the commencement, when the disease was in its infancy — not later. We employed bleeding simply as an adjuvant, and under such circumstances we employ it wisely. If, however, we wait until consolidation has taken place, bleeding does harm, no matter what be the form of pneumonia, whether croupous or catarrhal. If bleeding was performed in time, and on proper subjects, it was the great remedy in this disease.

Dr. Lester, of Michigan, did not think the practice of venesection so good as the theory. We did not bleed in cerebro-spinal meningitis, because we knew we should lose our patients; but we used the supporting treatment. He asked what was the difference between the two inflammatory conditions? He was surprised at so much advocacy of the lancet in pneumonia, and would like to see it dispensed with.

Dr. Martin, of Massachusetts, trusted that it might go out to the world that the American Medical Association sanctions the *occasional* use of the lancet, at least.

Dr. Wile, of Connecticut, in closing the discussion, expressed his gratitude for the courteous manner in which his paper had been discussed, and he accepted from the gentlemen their diagnosis of his cases. He felt delighted to learn that pneumonia was such a pleasant disease to treat as those gentlemen who prescribed the lancet seemed to think it. The cases he had reported were of the class, and the only class, he had met with in Connecticut. He did not wish to be understood as saying that the lancet was the only mode of treating pneumonia, but that it was the only way of treating those cases of pneumonia with which he had come into contact in Connecticut.

On motion of Dr. Gross, adjourned.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 30, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 3038 (no return from St. Louis or Buffalo); 1129 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 710, consumption 483, lung diseases 392, diphtheria and croup 201, scarlet fever 133, small-pox 69, diarrhoeal diseases 72, cerebro-spinal meningitis 60, typhoid fever 41, measles 38, malarial fevers 25, erysipelas 20, typhus fever 18, whooping-cough 17, puerperal fever 16. From *diarrhoeal diseases*, Chicago 31, New York 19, Philadelphia five, New Orleans four, Brooklyn three, Boston and Baltimore two, Cincinnati, District of Columbia, Pittsburgh, Charleston, Attleborough, and Milford one. From *cerebro-spinal meningitis*, New York 19, Chicago 11, Pittsburgh 10, Milwaukee seven, Philadelphia four, Cincinnati two, Brooklyn, Baltimore, District of Columbia, Lowell, Worcester, Fall River, and Palmer one. From *typhoid fever*, Philadelphia nine, New York eight, Baltimore four, Chicago, Boston, and Pittsburgh three, District of Columbia, Lowell, and Lynn two, Cincinnati, Providence, New Haven, Worcester, and Holliston one. From *measles*, Cincinnati 12, New York seven, Chicago and New Orleans five, Boston three, Philadelphia, Baltimore, Pittsburgh, Milwaukee, Nashville, and Westfield one. From *malarial fevers*, New York 12, New Orleans five, Brooklyn three, Chicago, Baltimore, District of Columbia, Milwaukee, and Lowell one. From *erysipelas*, New York five, Baltimore four, Cincinnati three, Philadelphia two, Brooklyn, Chicago, Milwaukee, New Haven, Worcester, and Newburyport one. From *typhus fever*, New York 17, Philadelphia one. From *whooping-cough*, Philadelphia five, New York and Chicago four, Brooklyn, Baltimore, Nashville, and Worcester one. From *puerperal fever*, Boston three, Philadelphia, Brooklyn, Chicago, District of Columbia, and New Haven two, Pittsburgh, New Bedford, and Fitchburg one. The mortality from cerebro-spinal meningitis has decreased from 75 for the week ending April 23d to 60.

Nine cases of small-pox were reported in Brooklyn, 32 in Chicago, two in Cincinnati, two in New Orleans, four in Pitts-

burgh; diphtheria 31, scarlet fever 18 in Boston; scarlet fever 33, diphtheria eight in Milwaukee.

In 44 cities and towns of Massachusetts, with a population of 1,085,266 (population of the State 1,783,086), the total death-rate for the week was 22.39, against 21.26 and 21.43 for the previous two weeks.

For the week ending April 9th, in 149 German cities and towns, with an estimated population of 7,203,611, the death-rate was 26.3. Deaths reported 3992; under five 1790; pulmonary consumption 617, acute diseases of the respiratory organs 436, diarrhoeal diseases 144, diphtheria and croup 142, scarlet fever 78, typhoid fever 52, whooping-cough 45, puerperal fever 27, measles and r6theln 25, typhus fever (K6nigsberg four, Danzig, Thorn four, Posen, Braunschweig) 11, small-pox (K6nigsberg, Munich three, Celle, Essen, Berlin three) nine. The death-rates ranged from 15.1 in Metz to 35.7 in Munich; K6nigsberg 28.8; Breslau 34.7; Dresden 23.8; Berlin 24.8; Leipzig 22; Hamburg 23.1; Hanover 15.7; Bremen 27.8; Cologne 21.9; Frankfurt 20.1; Strasburg 27.9.

For the week ending April 16th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 22.9. Deaths reported 3343; acute diseases of the respiratory organs (London) 395, whooping-cough 93, measles 81, small-pox (London) 77, scarlet fever 65, fever 47, diarrhoea 31, diphtheria 15. The death-rates ranged from 14.8 in Brighton to 28.3 in Portsmouth; Bristol 19.7; Birmingham 20.3; London 23; Leeds 23.4; Manchester 24.5; Sheffield 24.7. In Edinburgh 20.1; Glasgow 22.5; Dublin 29.

In the 21 chief towns in Switzerland, for the week ending April 16th, population 479,934, there were 38 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 12, measles 10, diphtheria and croup nine, typhoid fever eight, small-pox two. The death-rate of Geneva was 25, Zurich 35.9, Basle 16.7, Berne 33.9, St. Mier 58.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 30, 1881, TO MAY 6, 1881.

MIDDLETON, J. V. D., major and surgeon. Granted leave of absence for one month. S. O. 78, Department of the East, May 2, 1881.

CALDWELL, D. G., captain and assistant surgeon. Relieved from duty at Fort Fred. Steele, Wyo., and assigned to duty at Fort Sanders, Wyo., as post surgeon, relieving Assistant Surgeon Kimball. S. O. 36, C. S., Department of the Platte.

LIPINCOTT, HENRY, captain and assistant surgeon. Having reported at these headquarters, is assigned to duty as post surgeon at Fort Niobrara, Nebr. S. O. 36, Department of the Platte, April 29, 1881.

KIMBALL, J. P., captain and assistant surgeon. Assigned to duty at Fort Sidney, Nebr., as post surgeon, relieving Assistant Surgeon Mosley. S. O. 36, C. S., Department of the Platte.

MOSELEY, E. B., captain and assistant surgeon. Assigned to duty as post surgeon at Fort Fetterman, Wyo. Ter. S. O. 36, C. S., Department of the Platte.

REED, W., captain and assistant surgeon. Relieved from duty at Fort Henry, Md., and to report to the commanding officer U. S. Barracks, D. C., for duty at that post. S. O. 76, Department of the East, April 29, 1881.

BURTON, H. G., first lieutenant and assistant surgeon. Relieved from duty at Fort Niagara, N. Y., and assigned to temporary duty at Fort Wadsworth, New York Harbor. S. O. 78, C. S., Department of the East.

WORCESTER NORTH DISTRICT MEDICAL SOCIETY.

THE Worcester North District Medical Society held its annual meeting at the Fitchburg Hotel, Fitchburg, April 26, 1881. The following officers were chosen: President, Dr. E. J. Sawyer, Gardner. Vice-President, Dr. J. P. Lynde, Athol. Secretary, Dr. F. W. Russell, Winchendon. Treasurer, Dr. E. P. Miller, Fitchburg. Commissioner of Trials, Dr. C. C. Field, Leominster. Counselors, Drs. Ira Russell, George Jewett, F. H. Thompson, George D. Colony, R. F. Andrews. Censors, Drs. J. M. Blood, A. L. Stickney, B. H. Hartwell, A. O. Hitchcock, J. M. Randall. Reporter, Dr. G. B. Swasey, Westmin-

ster. Committee on Ethics, Drs. R. F. Andrews, F. W. Adams, W. H. H. Shepard. Library Committee, Drs. F. H. Thompson, C. H. Rice, A. O. Hitchcock. Orator, 1882, Dr. J. M. Blood.

The annual dinner was served at the Fitchburg Hotel, at which a goodly number of ladies were present. The annual address was then delivered by Dr. Levi Pillsbury, of Fitchburg; subject, Sunshine and Shadows of Professional Life. Meeting adjourned.

G. B. SWASEY, Reporter.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the society will be held Monday evening, May 16th, at eight o'clock, in the hall of the Medical Library Association, 19 Boylston Place. Reader, Dr. J. L. Hildreth. Subject, A Case of Pylephlebitis.

M. H. RICHARDSON, M. D., Secretary.

THE list of members recently admitted, after the necessary examination, to the Royal College of Surgeons of England, contains the name of Walter Brewster Platt, M. D. Harvard, Boston, U. S. A.

BOOKS AND PAMPHLETS RECEIVED. — The Sanitary Care and Treatment of Children and their Diseases, being a Series of Five Essays by Drs. Elizabeth Garrett-Anderson, Samuel C. Busey, A. Jacobi, J. Forsyth Meigs, and J. Lewis Smith. Prepared by request of the Trustees of the Thomas Wilson Sanitarium of Baltimore, Md. Boston: Houghton, Mifflin & Co. 1881.

Constitutional Syphilis. A Critic Criticised. By G. M. B. Maughs, M. D. (Reprint.)

Transactions of the Medical Society of the State of New York for the Year 1880.

Bovine Tuberculosis in Man. An Account of the Pathology of Suspected Cases. By Charles Creighton, M. D. With Illustrations. London: Macmillan & Co. 1881.

De la Phtisie Pulmonaire et de sa Curabilité. Par Jean-Louis-Simon Joly, Docteur en Médecine. Paris: Librairie J. B. Baillière et Fils. 1881.

The Treatment of Certain Forms of Vocal Disability by the Application of the Principles of Voice Culture. By S. W. Langmaid, M. D. (Reprint.)

Original Articles.

CONNECTION OF CARDIAC AND RENAL DISEASE.¹

BY ROBERT T. EDES, M. D.

THE connection of cardiac and renal disease has almost from the beginning of the more accurate knowledge of the latter been a very interesting theme of speculation, and of late years has been the subject of some theories very important as to aetiology and diagnosis.

Some of these, which, although undoubtedly expressing much truth, have been pushed farther than the facts will warrant, I have ventured to criticise, partly in the light of literature and partly in that of my own experience and observation. Hypertrophy of the heart without valvular lesion was at a very early period recognized by Dr. Bright himself as a frequent accompaniment of the renal disease afterward known by his name. And not only this; he had already perceived that it was much the more common in that form now generally known as contracted, granular, or cirrhotic kidney, or interstitial nephritis, although he placed a different interpretation upon the coincidence from that now generally received. "It is observed," he says, "that hypertrophy of the heart seems in some degree to have kept pace with the advance of the disease in the kidneys; for in the majority of cases where the muscular power of the heart was increased the hardness and contraction of the kidneys bespoke the probability of a long continuance of the disease. Six cases are noted in which the heart was soft and flaccid, and four in which it was unusually small, and in most of these, though not in all, the disease of the kidneys had not proceeded to the stage of contraction and hardness."²

As knowledge of renal pathology increased it was perceived that this statement of Dr. Bright applied not to stages but to kinds of degeneration, and at present it is generally admitted that although we may occasionally find a hypertrophied heart associated with a "large white" kidney, or a contracted kidney with a heart not enlarged, yet the connection between the thickening of the heart muscle and the increase of connective tissue in the kidney is a very constant one.

Dr. Bright supposed the hypertrophy to be a sequence of the renal disease, and suggested two explanations. The first, which he favored himself, assumed, like one set of the more modern theories, an increased resistance to the passage of blood through the capillaries, and hence increased work for the heart and increase of its muscular power. The resistance to the blood was due to altered chemical relations with the capillary walls, brought about by a failure of the kidneys to remove excrementitious products. The second explanation was the directly irritant action of this same vitiated blood upon the heart itself.

The first theory, which certainly had much plausibility so long as the contracted kidney was regarded as the latest stage of the "large white," or mottled, falls of itself to the ground when we find that the hypertrophy is associated almost exclusively with a form of the disease which, so far as we can judge from the symptoms and the analysis of the urine, is attended with no more, and probably even less, difficulties in

the way of excretion than the other forms where no hypertrophy is found.

It has been clearly shown that in many cases contracting kidneys, although furnishing a urine in which the percentage of urea is decreased, fully make up the deficiency by an increased quantity.

On the other hand, those affections, such as simple atrophy or atrophy with dilatation (hydronephrosis), which arise from disease in the urinary passages rarely give rise to hypertrophy of the heart.

Experiments have recently been made³ in which a hypertrophy of the heart was observed to follow removal or functional destruction of one kidney. In young animals the remaining kidney usually increased in size and weight, so as to compensate for the loss; but where this failed to take place, the heart hypertrophied, in order, so the experimenters suppose, to drive the blood more rapidly through it, making up for loss of secreting surface by increased velocity.

We certainly have here some conditions of human pathology not very remotely counterfeited, and yet the experiments do not help us much in accounting for the connection we desire to trace.

The experiments most closely resemble those cases in which atrophy of one kidney is the result of partial or total occlusion of its ureter, in which, however, hypertrophy of the heart seldom occurs.

It is remarked by Senator⁴ that persons with renal calculi may be in good health, may eat enough to furnish an abundant supply of urea, and are beside liable to attacks of partial suppression of urine.

Consequently, he says that next to the forms of chronic nephritis, of all chronic urinary diseases, hypertrophy of the heart develops itself most rapidly in connection with stone in the kidney. After the loss of one kidney, if the nutrition is not interfered with, the development of hypertrophy depends solely upon whether the remaining kidney is able to perform the duties of both.

This compensation on the part of the healthy kidney is, however, usually very complete, as is shown, for instance, in Simon's cases of extirpation of one kidney. In many cases, at least, this is a functional compensation merely, not attended with hypertrophy of the other kidney or of the heart.

A case where nearly total destruction of one kidney was produced, not by a calculus but by constriction of its ureter in its passage through the base of the bladder, was reported here by the chairman some weeks ago. The remaining kidney was not noticeably enlarged, nor was the heart.

It might, however, be fairly objected that in this case the condition of the patient's nutrition was such as to forbid anything like hypertrophy.

A case which corresponds more nearly to the experimental conditions was the following:—

A middle-aged lady, nervous and peculiar for years, died of an acute, probably pyæmic, attack, originating in an inflamed ovary. The left ureter was impervious, and the left kidney, filled with a putty-like mass, had evidently been for a long time useless. The right kidney was rather large, with somewhat granular epithelium, but was not decidedly hypertrophied. The heart was not hypertrophied.

Both Grützner⁵ and Litten⁶ found injection of urea

² Guy's Hospital Reports, vol. i. p. 39.

into the blood to raise the pressure, but the latter was unable to produce any hypertrophy of the heart by a daily repetition of the process. In these experiments, however, the kidneys were intact, and it has been very properly remarked that the retention of so diffusible a substance as urea, when the kidneys are healthy and excreting a full amount of water, is highly improbable.

In parenchymatous nephritis, however, these conditions do not hold, and hence it is possible or even probable that in those few cases of this form of disease in which hypertrophy is observed it is traceable to the retention of urinary constituents, of which urea is the chief but perhaps not the only important one. Senator applies exactly the theory of Bright to a small minority of cases.

These observations, however, do not go far toward establishing this theory in *interstitial* nephritis, where the hypertrophy is the rule and not the exception; for although we have the two ends of the chain, hypertrophy of the heart and loss of secretive substance, the same or similar in the two sets of cases, the connecting link, accumulation from non-excretion of urea and other products, is not only not demonstrated, but can, in many cases, probably long after hypertrophy is developed, be proved to be absent.

Ewald,¹ indeed, who adopts the theory of Bright for all cases of hypertrophy, speaks of a higher percentage of urea being found in the blood in interstitial nephritis than in parenchymatous or in other diseases, but this can certainly have been true only in the later stages. Bartels has shown very clearly that the polyuria fully makes up for a deficient percentage of urea, and also speaks of many cases where it could not be obtained from the blood, although all of his analyses were made toward the last of the disease.

The theory of Traube was mechanical. He supposed that the resistance by which the tension, and consequently the work, of the heart was increased was due to a diminished capillary area in the kidneys. Aside from the improbability that obstruction of only two, and those not the largest, branches of the abdominal aorta would so permanently raise the pressure as to give rise to cardiac hypertrophy, it is doubtful if any great hindrance exists to the flow of blood even through a considerably contracted kidney. The greatly increased flow of light urine shows that the circulation must be going on without marked hindrance. Buhl² has shown the development of a collateral circulation, both in the kidney itself and in the capsule and surrounding tissues, to compensate for the atrophy gradually taking place in the interlobular arteries and Malpighian corpuscles. The explanation of Traube is generally recognized as insufficient.

Dr. Gull and Dr. Sutton put a new phase upon the question when they showed the existence of thickening in the arterioles, not of the kidney alone, but throughout the body. This thickening might undoubtedly be a sufficient cause for cardiac hypertrophy, but the proportion of cases in which the renal and cardiac disease coincide, without any disease of the arteries, is, although not very great, too large to be overlooked, and it is by no means certain that in many others the arterial disease precedes that of the heart.

Dr. George Johnson had previously called attention to the thickened muscular coat of the small arteries

in the kidneys, a hypertrophy which he referred to a stop-cock action on their part, checking the access of diseased blood to the tissues. He held the changes afterwards observed by Gull and Sutton to be the results of the method of preparation, but several observers have confirmed their views so far as the existence of a general arterial disease is concerned. Its intimate connection with interstitial nephritis, however, is not so generally admitted, and it is pointed out by Ewald that the disease found in the small vessels of the kidneys is not the same.

The change somewhat vaguely described by Gull and Sutton as arterio-capillary fibrosis is considered by later writers as endarteritis of the smallest arteries.

Somewhat connected with these observations, but having rather a clinical than a pathological interest, are the views of Mahomed. If correctly representing the facts they are of the highest practical importance, and even if somewhat exaggerated, as I think they are, they are deserving of careful study for purposes of prognosis or prophylaxis.

They consist chiefly in the recognition of the pulse of high tension, which has been long observed as a frequent concomitant, as the essential and earliest symptom in what he calls Bright's disease. The significance of the name, however, he greatly changes, both in the way of omission and addition; for while he excludes those forms of renal disease in which the epithelium is chiefly affected and shrinking has not taken place, forms which were certainly described and figured by Dr. Bright, on the other hand he talks of cases of *Bright's* disease in which the renal lesion does not exist. The propriety of such a very forced change in the generally accepted and, as it seems to me, natural application of the name, is more than doubtful.

What Dr. Bright described and figured ought to be Bright's disease. If Mahomed has been successful in establishing the existence of a well-marked clinical and pathological group, in which some cases of renal disease and some other cases in which renal disease does not exist are both included, it ought to be called by the name not of Bright, but of Mahomed, just as some of the Germans have already christened the arterio-capillary fibrosis, which may or may not be connected with nephritis, Gull-Sutton's disease.

According to Mahomed, this increased arterial tension, which is most easily and certainly recognized by the sphygmograph, is due to increased resistance to the passage of poisoned blood through the capillaries, the poison being generated by scarlatina, pregnancy, lead, alcohol, gout, and "other well-known causes of Bright's disease," among which he would probably include cold and dampness. Hence hypertrophy of the heart.

This view differs from that one of Dr. Bright's alternatives which we have already discussed in the sequence of phenomena. According to Bright it was — renal disease, poisoning of blood from imperfect depuration, increased resistance, hypertrophy of heart.

According to Mahomed we have *first* the blood poisoning and obstruction, and afterward increased tension, hypertrophy of the heart, and arterial and renal disease.

Another explanation is closely allied to the second alternative of Dr. Bright, though with a similar reversal of cause and effect.

It is that offered by Debove and Letalle in Paris, and Buhl in Munich.

According to this, a myocarditis coexisting with, but

¹ Virchow's Archiv, vol. lxxi.

² Mittheilungen aus dem Pathologischen Institut zu München, 1878.

not dependent directly upon, the renal lesion gives rise to the hypertrophy and finally to arterial changes.

Debove and Letulle speak of this interstitial myocarditis, the increase of connective tissue in the heart, as demonstrable chiefly in the papillary muscles, but frequently to be found in other parts of the heart by hardening and thin sections.

Buhl relies rather on marks of old endocarditis and pericarditis, not affecting the valvular integrity of the organ, to prove the probable former existence of muscular inflammation.

This leads in the first place to simple dilatation, but afterward, partly by the increased nutritive activity which usually follows inflammation, but still more by the disproportion which is thus made to exist between the capacity of the dilated ventricle and the diameter of the undilated aortic orifice, to the greater or less degree of hypertrophy. The labor of the ventricle, and consequently the tendency to hypertrophy, is increased, according to Buhl, though I confess I cannot see why, by the anæmia so constantly present.

The statements of Debove and Letulle as to the frequent occurrence of interstitial myocarditis have hardly excited as yet attention enough to be fully tested in the way which they demand. A mere naked-eye inspection of the heart without preparation is not sufficient to disprove the existence of this lesion, and the silence of autopsy records, even minute and careful ones, where myocarditis has not been specially looked for, can therefore count for but little as evidence.

It is fair to suppose, however, that a case reported in Paris during the year in which these observers published some of their results was subjected to sufficient scrutiny to make the statement of "no cirrhosis" of the heart of some value. Such a case was reported by Barrie and Du Castel, in the *Progrès médical* (1879, page 467). It was a typical case of interstitial nephritis, with the *bruit de galop*, uræmia, anæmia, and Cheyne-Stokes respiration, the granular kidneys weighing 115 and 150 grammes, with arteries thickened and stiff. The heart weighed 810 grammes (27 ounces), and it is expressly stated that there was no fatty degeneration or cirrhosis.

The view of Buhl, who seeks to prove myocarditis, not by a remaining hypertrophy of fibrous tissue, but by traces of superficial inflammation, cannot very easily be either accepted or rejected. He himself admits that even these traces are absent in twenty per cent. out of the ninety-two per cent. in which hypertrophy of the heart is found.

The very frequent occurrence of arterial and cardiac disease, beside hypertrophy, is a fact not generally overlooked, but possibly not estimated at its real importance. Of fifty-eight cases of interstitial nephritis of which I have notes, in forty-six hypertrophy of the heart was present, and of these twenty were noted as having some other cardiac or vascular lesion, — in the majority of cases atheroma.

I do not in the least believe that this last figure at all represents the actual number of cases in which slighter lesions were present, but were not noted. It seems to me a rare thing, though I cannot speak by the book, to find a case of cirrhotic kidney with hypertrophy of the heart in which no other lesion evident to the naked eye is present.

Buhl describes the hypertrophy of the heart as usually beginning in a definite attack of subacute carditis, which may last six or eight weeks, or even one fourth

or one half of a year. It is as impossible to deny that this may take place as to affirm that it always does. The symptoms of myocarditis are so obscure that if it occur uncomplicated with either peri- or endocarditis, it may perfectly well fail of recognition, or even of giving rise to a train of symptoms which the most minute inquiry afterward can show to be at all characteristic. Buhl does not intimate upon what clinical basis this statement is founded.

Another possible link between the two affections may be found in certain nervous lesions recently described.

Da Costa and Longstreth¹ have found in many cases of renal disease, and especially with the contracting kidney, that a fibroid thickening with atrophy of cells is present in the renal ganglia. Banti, without knowledge of Da Costa and Longstreth's observations, has fully confirmed their data.²

Thoma³ has pointed out alterations of the nervous ganglia in valvular disease of the heart: in slighter cases hyperæmia and "granulating" inflammation, in older ones interstitial inflammation and increase of connective tissue, with fatty and pigmentary degeneration of cells.

Mahomed admits that the increased tension which, according to his theory, is at the bottom of the cardiovascular changes, may in many cases be of nervous origin; and Dr. Clifford Allbutt has pointed out the frequency of mental strain and depression as a cause of granular atrophy. The existence of high tension in several nervous affections will be noted in several of the sphygmograms exhibited.

Pathological anatomy alone can hardly decide which of these theories, if any, most correctly explains the facts. The coincidence of renal, cardiac, and arterial disease in the later stages being admitted, much must depend upon the time at which they are severally developed, or rather at which they can be shown to exist; and this, except in the few accidental cases of death at early periods of the disease, is a matter for clinical observation.

Mahomed's theory depends largely upon his observations of the pulse by means of the sphygmograph; and I have ventured to compare with his conclusions, which have been very distinctly expressed and carefully recorded, some of my own observations upon the pulse of Bright's disease and that in some other affections, as well as variations of the presumably healthy pulse.

Dr. Mahomed says,⁴ "The pulse tracing of each individual in health possesses a constant form dependent chiefly upon the constitution and general habits; it may be hard or soft, large or small, good or bad tone, excitable or phlegmatic, and is as characteristic as the tone of voice or mode of carriage, but in disease the pulse loses this individual form, and varies with the general conditions."

This may be true within certain limits and in regard to certain points, but in regard to the tension, which is the point upon which he lays chief stress in the diagnosis of Bright's disease, it does not correspond with my observations, chiefly upon my own pulse. This varies greatly from time to time, for certain reasons, some of which only are known to me.

SPHYGMOGRAPHIC TRACINGS.

1. C. H. W. Typical case of contracting kidney. Abundant urine; albumen; casts; hemiplegia; retinitis; hypertrophied heart; contracted kidney.¹

2. H. C. W. Acute gouty attack.

3. H. C. W. Urine 1010, double the normal quantity; no albumen; no casts.

4. W. C. Phthisis and parenchymatous nephritis. Hypertrophied right heart.¹

5. E. McD. Anæmia, vomiting. Urine 1006; albumen; casts.

6. F. H. Urine 1007; albumen; small quantity; casts.¹

7. J. C. Convulsions. Œdema. Urine 1009; albumen; granular and waxy casts.

8. J. R. Has had gout. Headache; no œdema; urine copious; small amount of albumen; a few hyaline casts.

9. M. S. Slight œdema, headache. Urine 1005; trace of albumen; no casts.

10. J. H. Debility, vomiting. Trace of albumen; Caö. Recovery.

11. M. F. W. Extreme debility, vomiting, anæmia. Urine 1020; possible trace of albumen; Caö. Recovery.

12. P. P. Abscess right frontal lobe. Urine 1020; albumen and casts.¹

13. P. W. Tumor (probably syphilitic) right temporal lobe. No hypertrophy of heart; much albumen; possible slight interstitial nephritis.¹

14. E. A. Neurasthenia.

15. June, 1879. Active professional man, apparently in excellent health.

16. Medical student.

17. Self. Cold after reading in bed.

18. Same. After cold bath.

19. Same. After breakfast same day.

20. E. H. Acute nephritis, œdema. Blood; albumen; casts.

21. Same. Urine 1023; some albumen and casts. Temperature somewhat raised.

22. Acute nephritis, much œdema. Urine 1010; albumen; blood casts.

23. Acute nephritis. Urine smoky; albumen; blood; casts.

¹ Autopsy.

Exercise produces a decided and great fall of tension. So does in a less degree a full meal. On the other hand, rest or quiet raises it; and the same is true, as has already been pointed out by Marey and others, of cold. In my own case, sitting at my writing-table for an hour or two in the evening, especially if the room becomes a little chilly, gives a tracing of high tension with tolerably strong action of the heart. I have found the same condition after reading in bed for an hour, especially, I recollect, on one occasion, when my feet did not get warm for the whole time. A cold bath sends the tension rapidly up, but if the reaction take place fully, this condition lasts but a short time. (See Nos. 17, 18, 19.)

I have sometimes thought that possibly a diurnal variation might be made out, the tension being lower during the forenoon and middle of the day, and higher in the evening, night, and early morning.

These periods would not be very far from corresponding with the diurnal periods of high and low body temperature,¹ but it would not be easy to separate such a fluctuation from the effects of exercise, food, and external temperature.

The two propositions of Mahomed, which are most strictly of a clinical character, most accessible to criticism, and in fact really constitute the foundation of his theory, are as follows:²—

“High tension may exist without renal disease, though rarely.

“Renal disease may exist without high tension, but also rarely.”

If it can be shown that these exceptions are very far from being rare, it seems to me that the practical importance of the frequent coincidence of high tension and renal disease is greatly diminished, whatever we may think of the importance of the new disease set up in place of the old.

It is obviously necessary to establish some sort of standard as to what shall be called high or too high tension, as indicated by the sphygmograph. Certain arbitrary rules as to the measurement of the tracing cannot be too strictly applied, and would often, without some allowance, lead to error; for the form varies more or less with the construction of the instrument, more especially the stiffness of the spring which receives the first impulse of the artery, and also with the pressure brought to bear. The tracings which I have taken mostly differ from Mahomed in their lesser height, but exhibit all the points usually brought out by any instrument. They resemble in their degree of amplification more those of Marey than of Mahomed. The prolongation of the tidal wave, the height of the aortic notch, and the development of diastolic can, however, all be studied upon them, and I think they can, with a little care, be very fairly compared with those of Mahomed. The pressure I have never taken the trouble to record, because, first, I have usually varied it enough to be sure that I was getting the best tracing; and secondly, because the pressure marked on Pond's instrument does not indicate the pressure brought to bear on the artery, but only on adjacent tissues, such as the tendon of the flexor carpi radialis and the radius itself, to say nothing of skin and fascia.

Tracings taken from presumably healthy persons vary within quite wide limits as to tension. In every group of such persons of whom I have tracings, I find

several with mark supposed to indicate a tension higher than the average or higher than normal. Some are not easily to be distinguished from those taken in chronic nephritis.

Among twenty medical students and ten or a dozen physicians of various ages, all presumably in good health, may be found quite a number of tracings with the prolongation of the summit, which is supposed to indicate the slower forcing of the blood into the arteries against a high pressure, and in some the elevation of the aortic notch and flattening of the diastolic wave, which indicate a tense condition of the arterial walls. (See No. 16.)

Of some twenty odd patients at the Adams Nervine Asylum, mostly young or middle-aged women, in none of whom was any renal disease detected, nearly every one showed similar characteristics. (See No. 14.) These I do not speak of as healthy, but simply as non-renal and non-cardiac.

Two professional men, aged about sixty and sixty-five, whose tracings, taken nearly two years ago, showed such marks of high tension, that, having formed my opinion rather from reading than from my own observation, I took special pains not to point out their characteristics, are still actively engaged in laborious practices, certainly retain unimpaired cheerfulness and excellent appetites, and, so far as one can judge without impertinent inquiries, are not in the least troubled with any symptoms of renal derangement. (See No. 15.) Of my own pulse I have already spoken.

An upholder of Mahomed's theory would probably remark upon these observations that what I have taken to be the pulse of high tension is not really so, or rather is not *high enough* to have diagnostic importance.

My reply would be: I am aware that in these cases we have not the marks of *extreme* high tension, but that it is fair to make use of them in criticising Mahomed's theory may be shown by a comparison of the tracings actually given by him as characteristic with those I shall exhibit. I think that upon the basis of his tracings as well as my own we may make four classes:—

(1.) Extreme high tension, found chiefly in acute nephritis, sometimes in chronic, in some doubtful cases. (In angina pectoris?)

(2.) Moderately high tension, found in chronic nephritis, in many nervous diseases, in pregnancy, often in health.

(3.) Moderately low tension, found in many diseases, but chiefly in health.

(4.) Very low tension, in debility, in fever, soon after vigorous exercise, after nitrite of amyl.

The tracings given by Mahomed³ are nearly all of a very moderate tension with the exception of those from acute cases. We frequently miss even in those selected to prove the correctness of his views, the prolongation of the tidal wave, as well as the high position of the aortic notch, and the more or less complete suppression of diastolic. It is of course higher in some than in others, but in none does it present the extreme characteristics observable in acute cases.

The tracings from cases of scarlatinal nephritis or, perhaps, scarlet fever, I can parallel from acute non-scarlatinal nephritis, and these are, undoubtedly, of high tension, the *pulsus tardus et durus*, but with the improvement in the symptoms, or rather as their acuteness progresses, either toward recovery or toward a

¹ Jürgensen, Die Körperwärme des gesunden Menschen.

² Lancet, August 18, 1879.

³ Med. Chir. Trans., 1874, and Guy's Hospital Report, 1879.

chronic stage, this high tension subsides, as is seen both in Mahomed's tracings and in those from E. H. (Nos. 20, 21) for instance.

In the chronic cases, even the most typical, of interstitial nephritis, those in which we should expect the most pronounced high pressure, we find it only to an extent which can easily be paralleled, not, as Mahomed says, "rarely," but in various nervous diseases, including simple neurasthenia (*sit venia verbo*), and often in what, unless symptoms are very latent and remain so for years, we cannot help calling excellent health. This, however, it is fair to say, is admitted by Mahomed himself.}

It is true that a pulse of somewhat high tension is exceedingly common in chronic renal inflammation, possibly almost constant, except when certain special conditions, notably great debility or marked fever are present, as we see in that very frequent combination of phthisis and nephritis (see No. 4), or, as will be noticed, in the sphygmograms from H. C. W. (Nos. 2, 3), in intercurrent gouty attacks, but the position of Mahomed, that the "signs of high tension or overfullness of the arteries are the *only pathognomonic signs of chronic Bright's disease*," is absolutely untenable. If he means *extreme* high tension, we find it chiefly in the *acute cases*, those in which the diagnosis is easiest and the prognosis most favorable; if *moderately* high tension we find it too often elsewhere to be pathognomonic of anything. Suspicious is the strongest word which can properly be applied to it.

This may, perhaps, be as well shown by the accompanying tracings as by any extended description. I have placed, first well-marked cases of nephritis, the basis of the diagnosis being in brief, and, next, a number of other cases in which nearly the same indications of high tension are found, and in which the disease was of an entirely different character.

I do not wish to deny to this symptom all value either in diagnosis or prognosis, but I think that Mahomed has been led to overestimate it by his too exclusive consideration of acute nephritis, in which the maximum of high tension is found, and its subsequent passage into the chronic stage, and that in tracing a necessary connection between various other conditions of ill health, in which a moderately but still too high tension is found, and the fully developed granular kidney, he is going far beyond a sound basis of clinical observation.

Of course, he can, if he chooses, define Bright's disease as that condition in which too high arterial tension is found, and we shall then have no difficulty in admitting that high tension is pathognomonic of it, but such a disease, whatever its name, would coincide only here and there, and not of necessity with the affection described by Dr. Bright, and recognized under this name as a well-marked clinical type by the profession generally.

Acute nephritis, beginning with high tension, may undoubtedly often be traced directly into subacute or chronic nephritis, but that all other affections, as, for instance, some of a dyspeptic character, which are attended by a similar condition of the pulse, must necessarily lead to the same result, is a very arbitrary assumption.

Mahomed allows so long a time for the development of the disease foreshadowed by the presence of high tension, that the disproof of his theory is as difficult as he admits the proof to be. If, however, the persistent

high tension is the cause of the cardio-vascular changes, of which hypertrophy of the heart is certainly one of the most common and most prominent, this hypertrophy *should be* developed at a very early period. But Mahomed admits that it requires years, often many years, to produce in the dyspeptic and suspicious or the apparently healthy cases, which, on account of their pulse, he supposes *will* develop into Bright's disease, a hypertrophy of the heart and disease of the vessels. And yet in cases where nephritis is present it develops much more rapidly than this.

Traube states that he has seen hypertrophy distinctly developed in four weeks after the beginning of an acute nephritis.¹ It would certainly seem then that a functional high tension, not originating in disease of the heart and vessels, cannot be either the connecting link between or the common cause of the renal and the cardiac disease.

It is easier to criticise than to construct, and I have no new theory to propose in place of those which seem to me insufficient.

We cannot help seeing, however, the facts to which it is the merit of Johnson, of Gull and Sutton, and of Mahomed to have drawn our attention, that the form of Bright's disease attended with interstitial nephritis is more than renal, and that the cardiac and vascular changes may occupy the foreground of the clinical picture. We must also observe how often organic disease, more or less marked, occurs in other regions than in the muscle of the heart and in the kidney, the peri and endo-carditis, the pleuritic adhesions, the endarteritis of large and small vessels, diminishing their elasticity, and thus demanding an increased expenditure of force to drive a given amount of blood, the usual coincidence of a similar interstitial hyperplasia in the ganglia connected with the kidney, and possibly its not infrequent occurrence in the nervous centres and their membranes.

We are brought by these facts to admit the existence of a fibro-hyperplastic diathesis, with perhaps no special tendency to particular organs except so far as influenced by their functional activity, but since the heart and vessels among the muscular organs, and the kidneys among the secreting are more constantly active than any others, most frequently making itself manifest in these, with effects which vary with the different structure of the organs.

TWO CASES OF TEMPORARY APHASIA.

"BRIGHT'S DIATHESIS."²

BY T. M. ROTCH, M. D.

THE following somewhat unusual cases, occurring in my practice within a few weeks of each other, present points of clinical importance which may make them interesting to members of this society, who I hope can throw such additional light upon them from the resources of their own experience as to elucidate certain questions of aetiology and resulting diagnosis which I fear my own efforts at investigation have left rather doubtful.

The first case I supposed to be a disturbance of circulation in the third left frontal cerebral convolution, by

¹ Ges. Beitrage, etc., vol. iii. p. 239.

² Read before the Society for Medical Improvement, May 9, 1881.

a minute embolus or blood clot being carried from the aortic orifice to one of the smaller branches of the left middle cerebral artery, producing complete aphasia, with the exception possibly of the word "yes," and apparently without disturbance of articulation or muscular paralysis of any kind, lasting about twenty-four hours, and resulting in complete recovery. The second case was one of partial aphasia without muscular paralysis, apparently arising from disturbance of the cerebral circulation by abnormal blood or a minute hemorrhage, lasting several days, and resulting in entire recovery so far as the cerebral symptoms were concerned.

CASE I. Mr. A., age fifty-nine, is of an exceedingly nervous temperament and has been a good deal broken down by business troubles during the last five years. He had articular rheumatism about fifteen years ago, but seemed to get entirely well, and since that time has had no symptoms referable to the sequelae of that disease, and has been strong and well excepting that for the last ten years he has suffered from headaches affecting the whole head, and not especially localized; at times these headaches have been accompanied by nausea, but this is not a constant symptom.

One year ago he had an acute attack of tonsillitis and pharyngitis, during which he was delirious for a number of days without any other apparent cause than general disturbance produced by the high temperature, which ranged from 39° to 40° C. The physician with whom I saw him in consultation at that time failed to detect, on repeated examination, anything abnormal in the urine or any cardiac complication; I myself did not make any physical examination.

Mr. A. recovered entirely from this attack, and has since been pretty well with the exception of occasional headaches, which have seemed to be connected with digestive disturbance. His bowels are usually constipated, and he has had hemorrhoids for the past two years. Since the attack of tonsillitis he has at times been troubled with twitching of the legs on sitting still for some time. He has never had syphilis, and is not in the habit of drinking liquors.

December 30, 1880. Mr. A. came into my office to ask a question at nine A. M., conversed naturally, looked well, and said that he felt in good condition. After speaking of the extreme cold (it being one of the most severe days of the winter) he returned to his home, a distance of a few hundred yards. On his arrival he is reported to have had difficulty in finding words to express himself, though his mind seemed perfectly clear. He complained of headache, which was somewhat relieved by the application of mustard to the back of the neck and to the feet; he also spoke of slight numbness of the back of the right hand lasting for a few minutes. I saw him an hour afterwards. He was then complaining of a slight pain in the front of the head; his mind was clear, and he spoke pretty well, with no difficulty in articulation; but every now and then he failed to obtain certain words in expressing himself, and he intelligently drew my attention to this phenomenon, asking me "if it was paralysis." The pulse was 65, regular and soft. The skin was normal to the touch. The tongue was protruded straight. There was no difference in the pupils, which contracted well. There was no numbness, paralysis, or disturbance of sensation.

I was obliged to leave Mr. A. for some hours and did not again see him until evening, when I met Dr.

Samuel Cabot in consultation, Dr. Cabot also having kindly consented to see the patient during my absence. Dr. Cabot reported that after I had left him in the morning, Mr. A. began to have more headache, which soon became intense, and in about an hour he entirely lost the power of speech; he passed at this time a large amount of light-colored urine, and at one time became very pale, being almost in a state of collapse, and ammonia was given to revive him.

At six P. M. he was actively delirious, attempting to get out of bed. He did not recognize any one, but seemed to hear, and answered "yes" to all questions. His face and head were flushed and hot. Pulse 120, bounding, full, but not particularly tense. Respirations regular, 24. The heart was beating regularly but forcibly. The cardiac dullness was slightly increased to the left, corresponding to the apex beat, which was in the mammary line and a little lower than normal. A loud souffle, drowning both heart sounds, was heard all over the cardiac region, and by Dr. Cabot also in the axillary line, but not accurately localized. The urine was passed involuntarily, and he groaned as if in great pain. No paralysis was apparent. The skin of the body and extremities was extremely sensitive, the slightest touch apparently annoying him.

Mr. A. continued in this state until ten P. M., when he went to sleep. Respirations 24, regular; temperature 38.8° C.; pulse 120, rhythmical, full, and rather tense. At 2.30 A. M. he sat up in bed and passed his water in a bed pan, but did not recognize any one, and soon went to sleep again, not appearing to suffer pain. He used his legs and arms well, and nothing abnormal was noticed about his face or eyes.

When asleep and lying on his back a slight catch was noticed in his breathing.

The heart was still found to be beating violently, and the souffle, now not so loud and more localized, was heard in the second intercostal space, close to the right parasternal line and with the first sound.

December 31st, seven A. M. He seemed to notice that there was a strange nurse in the room, but when spoken to he could only answer "yes." At nine A. M. the pulse was 120, and not so full and tense; the temperature was 37.2° C. He recognized his friends, spoke a few words, and was easily persuaded to go to sleep. The urine by estimate was rather lessened in amount, darker than normal, with a slight flocculent sediment; specific gravity 1030, reaction acid, no sugar, albumen in considerable amount; after standing for several hours the urine was found to contain a heavy precipitate of amorphous urates, urate of ammonia, oxalate of lime crystals, and numerous hyaline and granular casts.

At six P. M. Mr. A. was found to have recovered the use of words entirely, and was reported to have slept, with occasional intervals, all day.

January 1, 1881, nine A. M. He was reported to have had a good night and now takes milk and water, not having had, before this, anything to eat or drink for forty-eight hours. The bowels were moved by an enema.

January 3d. Since the last report Mr. A. has remained in bed, sleeping most of the time, but feeling well and having a good appetite, milk being given to him every two hours when awake.

He has at times complained of flashes of pain in the front and back part of his head, passing off, however, in a few minutes. Pulse 75, a little full, and, as estimated

by the finger, of rather higher tension than normal. The patient was very nervous and asked a great many questions about himself, so that it was deemed best not to examine him much, and for this reason a sphygmographic tracing could not be obtained. The albumen in the urine was found to be lessened, and the amount passed in twenty-four hours 556 cc. (about 519½).

January 4th. The pulse was 69 and not so full. Temperature 37.2° C. Amount of twenty-four hours' urine 624 cc. From this time there were no unpleasant symptoms, the patient rapidly recovering his strength, and the only points of interest in the case being the analysis of the urine and the examination of the heart.

January 5th. Urine, amount 619 cc. (about 522); color about normal; reaction acid; specific gravity 1022; albumen, a trace; uric acid in large amount; a few granular casts.

January 6th. Urine, amount 737 cc. (about 525½); albumen, none; uric acid less in amount; oxalate of lime crystals less numerous; oxalate of urea crystals, a small number; a few white corpuscles, a slight amount of epithelium from the bladder, and a few granular casts.

An examination of the heart showed the apex beat to be a little depressed and in the mammary line, and the area of absolute cardiac dullness slightly increased in the vertical diameter downwards, corresponding to the displaced apex.

The valvular sounds at the heart's apex were normal, as they were over the whole cardiac area, excepting that in the second right intercostal space close to the right parasternal line a soft murmur was heard replacing the first sound of the heart, the second sound being normal.

The pulse was 66, a little full, but soft and regular. The lungs were normal.

January 7th. Urine, amount, 1087+ cc. (about 537½).

January 8th. Urine, amount, 1116 cc. (about 539).

January 9th. Urine, amount, 1087 cc. (about 537).

The patient was walking about, and taking solid food.

January 10th. Urine, amount, 1087 cc. (about 537).

January 11th. Urine, amount, 1327 cc. (about 547).

January 12th. Urine, amount, 1175 cc., normal; specific gravity 1011; color rather lighter than normal; no albumen; no uric acid or any abnormal sediment; no casts.

Mr. A. on this day reported that he had at times had a little spasmodic headache, but that he felt perfectly well, and had been out and about as usual. He was looking well, and conversed with his usual command of language. I have seen him within a few days, and he has had no return of the headaches, which were so troublesome before his illness.

CASE II. Mr. B., age forty-five, has always since adult life been strong and well with the exception of an attack similar to that from which he is at present suffering, occurring three years ago, and of double pneumonia two years ago. When a boy he had something the matter with one of his knees, which swelled, became painful, discharged pieces of bone, and after incapacitating him from walking for over two years, finally recovered entirely without ankylosis. He has had other diseases of childhood, but no unfavorable sequelae. Mr. B.'s sister informed me by letter in regard to their father, as follows: "He had always been strong and well, showing remarkable mental

energy in a long professional career, until, when quite an old man (the exact age was not stated), he had an attack of paralysis, which affected his speech, but he was at all times able to make known his immediate wants; this attack was preceded by a "thumping" pain in the back of his head, but, with this exception, he was often heard to say that he never suffered from headache. After a time, he regained his speech, and continued his work. He never had anything the matter with his kidneys so far as was known, and finally, when in his usual health, had an attack of apoplexy, from which he died in a few days."

Mr. B. has never had syphilis, and has led a temperate life, excepting that the daily amount of liquor which he has for many years been accustomed to take is greater than would be considered within the limits of safety for health.

He is subject to rheumatic pains in various parts of the body, and at times in the feet, causing lameness and swelling without pitting. He has never had rheumatic fever, or a decided attack of gout. He has at times noticed a swelling of the glands on either side of his neck, and not accompanied with pain or enlargement of the tonsils. Three years ago, when in active business in New York, after working very hard, and undergoing great mental anxiety, he felt dull and uncomfortable for several days, and finally "fainted," as he expressed it; on coming to himself he found that he had lost the memory of words, and that his sight was affected, all colors looking very brilliant, and peripheral vision being impaired; a friend who came into his room looked as if he was surrounded with violet flames. This disturbance of the eyes passed off in a few days, and his aphasia soon disappeared, leaving him as well as ever until the present attack.

Mr. B. has been feeling very well, but during the absence of his partner he has had great responsibilities thrown upon him, and has had considerable mental strain.

February 21st, when called to see Mr. B., I found that he was unable to give a very clear account of what he had been doing on the previous day, and that although he had no paralysis of articulation he could not recall the words which he wished to use; he said, however, that he had passed a very restless night; had got up several times to pass his water, and was nauseated for a short time, but did not vomit. A clerk, who is employed by Mr. B., told me that he reached the office much later than usual February 21st, and said that he did not feel well; he was unable to tell his partner, who had just returned from New York, to whom he had given checks during his absence, and he entirely failed to give the accustomed combination of the safe; he seemed confused, and had to be sent home a few hours before I saw him. His partner, who came into the room during my visit, stated that he had noticed that for the last few months Mr. B. had been inexact in his interest computations, where before he had been remarkably clear-headed, and that while he usually was very good-natured, he had lately been peevish, and a little sullen. When I first saw Mr. B., February 21st, his face was flushed, and he had a hesitating, embarrassed manner, due, apparently, to his inability to express himself freely; he protruded his tongue, which was considerably coated, straight, and without tremulousness; the pharynx was reddened; the tonsils were not enlarged, but the lateral cervical glands were somewhat swollen. There was no paraly-

sis or disturbance of sensation; he could walk well with his eyes shut and without dizziness; the bowels were regular; he stated that so far as he knew he had never had any trouble with the bladder, but that he was accustomed to get up in the night to pass his water, and that for the past twenty-four hours he had been passing a greater quantity of urine than usual. The pulse was 90, full, and, as estimated by the finger, of increased tension; the temperature was 38° C.; respirations regular and quiet. He was perspiring quite freely, and complained of soreness in both temporal regions. The lungs were normal. The heart's apex was in the mammary line, a little below its normal position, and its dullness was somewhat increased, corresponding to the displaced apex. The mitral sounds were about normal, though the first sound had a tendency to reduplicate; the second aortic sound was slightly accentuated; no murmurs were heard. The

hearing was good; the eyesight was somewhat affected, objects not looking clear. On asking Mr. B. what he had had for breakfast, he said that he could not remember the name, though he plainly saw the object mentally; he also said that he thought it would be impossible for him to write or read, and that he did not wish to try.

February 22d. The patient reported that he had slept well, but that he had been up two or three times in the night to empty his bladder. The soreness complained of yesterday is now especially over the left temple. He talked rationally, but was still unable to get certain words. He referred to his inability to obtain the word representing his breakfast yesterday, but after thinking for about ten minutes he said it was "fish-balls." Pulse 90; temperature 37° C. He was unable to write clearly, as shown by Papers I. and II., a note which he attempted to write at my dictation, in which he was to say, Dear Sir, — I shall be down town to-morrow morning. Business is flourishing.

I. (First attempt) Dir Sir, — I shal be harn down star.

II. (Second attempt.) Dear Sir, — I shall be down stone to morion morning. Bisiniss is sforishing.

February 23d. An examination of the urine gave an acid reaction; specific gravity 1010; no sediment; considerable albumen; a few hyaline casts.

February 24th. Reported that he felt much better, and that at times he had no pain in his head, and that when it was present it was relieved in a short time by taking eight grains of acetate of potash in half a tumbler of water. His mind was much more clear and he wrote intelligibly, but with an effort, as seen in paper III.

He complained of pain in his shoulders and legs. The swelling of the cervical glands had disappeared, and the throat was less reddened.

February 25th. Mind perfectly clear; writing, according to his partner, about as legible and free as usual, as shown in paper IV.

Urine: amount passed in twenty four hours 1504 cc., about 551; color lighter than normal; specific gravity 1010; reaction acid; albumen in slight amount; no sediment to the eye. Complained of pain in left instep, causing lameness. No swelling detected.

I.

Dear Sir

Dir sir

I shal be

harn down star.

II.

Dear Sir

I shall be

down stone to morion

morning - Business
is sforishing - Yours
truly

III.

Dear Sir

I am coming down
town tommorn - Business
is flourishing & I am feeling
much better

February 26th. Dr. Wadsworth saw the patient in consultation, and reported that there was nothing found in the eyes which pointed to cerebral disease, but that the veins were rather large, and there was an evident pulsation in one of the arteries coming from the disc similar to that which is seen in aortic regurgitation.

One of the arterial branches also gave an appearance of obliteration for a short distance. Dr. James J. Putnam, who saw the patient in consultation, took a sphygmographic tracing of the pulse, which is represented in diagrams 2 and 3, diagram 1 representing the normal pulse.

IV.

My Dear Doctor;
As you are at present somewhat interested in my productions, I herewith send you two of them - this note & the contents of a certain bottle - which contents I trust have been made in the highest style of art I cannot say so of this note.
Very Respectfully

February 28th. Dr. William B. Hills made the following report of the urine: amount in twenty-four

DIAGRAM 1.

DIAGRAM 2.

DIAGRAM 3.

hours 1845 cc., that is, increased; color normal; reaction acid; specific gravity 1012½; albumen a trace; bile pigments and sugar absent; sediment, quite nu-

merous round cells (pus), occasional renal epithelium, a few hyaline casts; urea 30.5 grammes, that is, practically normal. Dr. Hills remarked that the fact that

DIAGRAM 4.

the urea was about normal led him to think that if an interstitial nephritis was present it was in a very early stage, but from the large amount of the urine in connection with the general symptoms he did not think that there was much doubt but that an interstitial nephritis existed, though possibly this patient might normally pass a large amount of urine, and the casts might be due to a congested kidney.

April 17th. The patient, having in the mean time given up alcoholic drinks, lived simply, and undergone a mild purgative treatment for two weeks, reported that he had been very well, and had been working as usual. Dr. Putnam took another sphygmographic tracing, which resulted as shown in diagram 4.

April 22d. The patient having begun to take a tonic of iron and nux vomica, some doubt was thrown on the correctness of the deductions which had been made from the analysis of the urine, from Mr. B.'s remarking that he might in measuring the urine have preserved more than the actual twenty-

four hours' amount, and another careful examination was made by Dr. Hills. Urine: total amount 1370 cc.; color normal; specific gravity 1013; reaction acid; amount of sediment slight; chlorides normal; total amount of urea 26.7 grammes; albumen a trace, but a little larger in amount than at previous examination.

Under the microscope were seen numerous round cells (pus), a small amount of renal epithelium. Hyaline casts more numerous than at previous examination.

Dr. Hills writes as follows concerning the case:—

This examination following the history of the case as given to me by Dr. Rotch strengthens me in my opinion that this is a case of chronic Bright's disease (probably interstitial) rather than a case of congestion merely. I base my opinion on the amount of urea, which is one fifth to one fourth below the average normal amount, which would not be expected in a person up and about every day, unless there was some structural disease of the kidneys. The amount of urine, 1370 cc., cannot be considered much, if any, diminished, unless we know that his average normal quantity is above this, as it quite often is the case that the normal amount of urine is as low as this. I do not know that I should be justified, from my analyses thus far, in giving an opinion which would be considered of any value as regards the stage of the disease. I should be inclined, however, to consider the disease to be in a comparatively early stage rather than late.

(To be continued.)

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

MAY 9, 1881, DR. T. B. CURTIS presided.

DR. T. M. ROTCH read a paper, entitled

TWO CASES OF TEMPORARY APHASIA; BRIGHT'S DIATHESIS.¹

DR. WADSWORTH said in regard to the case which he had examined, that the throbbing of an artery in the fundus of the eye, especially where there is a curve in its course, as was the case in this one, was a phenomenon which he had seen quite frequently where there was no heart trouble, and as to the obliteration of the artery it was probably only where it dipped into the surrounding tissue, and could hardly point to an embolus.

DR. R. T. EDES read a paper on

THE CONNECTION OF CARDIAC HYPERTROPHY AND RENAL DISEASE.²

DR. J. J. PUTNAM said the normal pulses which he had examined had never shown evidence of high tension to such a degree as Dr. Edes had spoken of. In the cases of high tension pulse which he had met with, he almost always found those general symptoms spoken of by Mahomed, though the urine did not by any means always show evidence of renal disease. The cases of lead poisoning examined at the Massachusetts General Hospital showed a high tension pulse. Dr. Putnam then reported the case of a woman with slight hemiplegia and difficulty in articulation, with slight aphasia, such as might have come from a clot in the process of absorption, but the pulse suggested an examination of the urine, which showed renal disease.

In Dr. Rotch's case the power of overcoming pressure was so great (about 300 grammes) that it would enhance the value of the communication for the gentlemen to feel the power needed to overcome the spring of the sphygmograph used in taking the tracing.

DR. FITZ thought that the value of the observations and criticisms presented by Dr. Edes was all the greater since they were corroborated by the experiments of Grawitz and Israel referred by to Dr. Rotch. These observers found that no increased arterial tension resulted from experiments producing granular atrophy of the kidney and hypertrophy of the heart. They also record that the resulting hypertrophy of the heart gave rise to dilatation of the arterial system where the walls of the arteries were in a normal condition. Since the typical forms of chronic interstitial nephritis are more common in people beyond middle life, and as the alterations of the larger arteries, in consequence of which they become thickened and rigid, are more common and extreme at the same period, it might be considered as not unlikely that increased arterial tension in cases of chronic interstitial nephritis is rather attributable to concurrent disease of the larger vessels than to alterations of the kidney or doubtful changes of the arterioles and capillaries in general.

DR. MINOT said that he had experimented on one patient with the solution of nitro-glycerine mentioned by Dr. Rotch, and that a drop of water seemed to produce about the same effect as the solution.

DR. DENNY spoke as follows: I have not infrequently noticed aphasia in epilepsy mitior and in hysterio-epilepsy, lasting from a few moments to several hours, in which cases a general neurosis, without local lesion, interrupts temporarily the functions of the cortical centres presiding over speech. Again, I have met with similar attacks in the general paralysis of the insane, in which epileptiform phenomena occur, but where in addition there is *diffuse* peri-encephalitis; also in epilepsy complicating syphilis, and lead poisoning, in which cases a *general* ischemia existed. It is an interesting question as to how a general neurosis, or a toxæmia, can thus centralize their action without local lesion. An explanation is suggested by Dr. William O'Neill,³ who cites a case of transitory aphasia, connected with convulsion, limited to the right side of the face, and right arm, which occurred in a man previously free from epilepsy and cerebral disease, after a protracted period of excessive drinking. He assumed that the alcohol rendered the blood incapable of absorbing oxygen, thus poisoning the nerve-centres, which toxic action was confined to so circumscribed a portion of the left frontal lobe because the man had been a great singer and speaker, and had thus developed an unusual blood supply in this part.

In another case in which transitory aphasia occurred several times, and once, after excitement in dispute, the post mortem failed to find anything abnormal in the brain.⁴

The same toxæmic action, in effect, which produces aphasia in lead poisoning and in alcoholism may likewise operate in Bright's disease.

In one case of Bright's disease in which epileptiform seizures at very rare intervals occurred, I found a total loss of the memory of words, as signs of ideas (aphasia amnesia), to the following extent:—

The patient, a man forty years of age, of Ger-

¹ Vide page 462 of the JOURNAL.

² Vide page 457 of the JOURNAL.

³ Lancet, vol. ii. No. 9, 1879.

⁴ Ibid.

man birth, many years resident in America, usually talked English; he had an epileptiform seizure, and thereafter he talked exclusively in German, when one morning, several months after, he suddenly began conversation again in English. The urine was reduced to 800 cc., the urea much below the lowest health limit, and blood, pus, and albumen were noted in the analyses of Professor Wood.

The pulse, taken by myself, and subsequently repeated for some months by another physician, after the epileptiform attack was 40; it became about 80 after a month. This *pulsus tardus* is sometimes found when toxic agencies depress and retard the cardiac action.¹ The sphygmograph showed a tricrotic pulse of low tension.

In Bright's disease, and in ischæmic diseases, where, as in lead poisoning, an epileptiform neurosis may concur with toxæmia, even in a marked form, it may be assumed that transitory aphasia is not always at least dependent upon local lesions within the brain.

DR. A. T. CABOT said that some observations of Neilson² are of interest in connection with the fact noticed by Dr. Edes that in old persons a high tension at times exists in the arteries without cardiac or renal lesion. Neilson examined the capillaries in seventy-nine brains of persons dead from a variety of causes, and in fifty of these he found a change resembling that described by Gull and Sutton. Their walls were thickened and transparent for short stretches, particularly at points where they branched. This change he found almost invariably in the brains of old persons. Such a change of the finer vessels, assisted by the stiff condition of the larger vessels common in the old, might well account for the high tension noticed.

DR. THOMAS DWIGHT showed some

FROZEN SECTIONS OF HEADS

which he had made at the Harvard Medical School during the past winter. They were imbedded in plaster of Paris and kept under alcohol.

Dr. Dwight said that he would allude merely to some points in a median section of a head of a child. The third or pharyngeal tonsil was well shown. The uvula, lying on the back of the tongue, was within a quarter of an inch of the epiglottis. The tongue, being relaxed, had fallen backward, carrying the epiglottis with it, and consequently was in the position it may assume in profound anaesthesia, completely closing the air-passages. Dr. Dwight stated that he had made many other frozen sections during the past winter.

DR. A. T. CABOT showed

A CASE OF POSTERIOR TORTICOLLIS.

The patient, a child of six years, began to have a stiff neck about four years ago.

The head was gradually drawn over to the left shoulder upon which it rested for two years previous to last September when she entered the Children's Hospital.

The head at this time rested upon the left acromion, and this shoulder was raised somewhat as if to meet it. The parents state that at one time the head bent almost backwards, but later resumed its position towards the left side. The sterno-mastoids were not tense, but the nuchæ and other muscles of the nuchæ upon the affected side were contracted and resisted attempts at reposition. Under ether the head was brought into posi-

tion in the manner recommended by Delore, without the exercise of very great force; a plaster bandage was then applied over the shoulders and head, keeping it fixed in its proper position. This was kept on a month and then replaced by a simple wire frame, which, resting upon the shoulders, held the head up and resisted rotation. The child, who was much emaciated before the operation, and so weak that she could walk but a few steps without fatigue, rapidly gained flesh and strength, and early in January left the hospital still wearing the wire frame alluded to. This was continued on account of a feeling of weakness when without it. M. Delore,³ from whose description this method of treatment was adopted, says that in cases of torticollis dependent upon contraction of the posterior muscles of the neck the reposition under ether is always comparatively easy, the muscles offering but little resistance.

DR. BRADFORD said that he had seen the case reported by Dr. Cabot and could bear witness to the success of the treatment.

DR. TARBELL said "that he thought, from the history of the case and appearances this evening, there was something more than a simple torticollis. The child dislikes to have the apparatus removed, the muscles on both sides of the neck are equally rigid, the child will not rotate the head, and carries herself in a very careful manner, as if desiring to avoid any jar when the apparatus is taken off. There is also an apparently abnormal prominence of the spinous process of sixth or seventh cervical vertebra. All of which symptoms point strongly toward cervical caries. Moreover it is very unusual to have a torticollis of purely spasmodic origin without more or less affection of the sterno-cleido-mastoid muscle, and it was also very unusual to overcome the ordinary torticollis under ether so readily as Dr. Cabot states it was done in this case."

DR. CABOT afterwards stated that the child's dislike to having the apparatus removed was a new symptom, and that he had not seen the patient for some time previous to this evening.

He then said that "the slight prominence in the cervical region which seems to-night somewhat more marked than a month ago, when I last examined the patient, and when we thoroughly canvassed the question of cervical caries, together with the decided increase of the stiffness of the cervical muscles, makes the existence of disease of the vertebrae in this case more probable than we were then inclined to regard it."

DR. H. I. BOWDITCH reported for the committee on Dr. Jackson's portrait. The report will be published in the JOURNAL of next week.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

RICHMOND, May 4, 1881.

H. DISEASES OF CHILDREN.⁴—Chairman, Dr. A. Jacobi, of New York; secretary, Dr. T. M. Rotch, of Boston. Dr. H. I. Bowditch, of Boston, presented a paper entitled,

THE RELATIONS BETWEEN GROWTH AND DISEASE, of which the following is an abstract:—

After discussing the various influences which must be taken into consideration in approaching this impor-

¹ *Arch. der Heilk.*, vol. xvi., 1876, p. 100. ² *Arch. der Heilk.*, vol. xvi., 1876, p. 100.

³ *Gaz. Hôpitalaire*, March 15, 1878.

⁴ Specially reported for the JOURNAL.

tant subject, such as climate, race, social condition, occupation, and sex, Dr. Bowditch directed the attention of the medical profession to carrying out more extended observations on this subject, especially in the West, where the emigrant class, coming from different countries, presents especial advantages for this kind of investigation. He also spoke of the intention of the Massachusetts State Board of Health, Lunacy, and Charity, to distribute blank cards and circulars of instruction to aid in this work, and stated that it was probable that the National Board of Health would soon undertake a similar work on a larger scale. Dr. Bowditch said that it seemed probable that the accurate determination of the normal rate of growth in children would not only throw light upon the nature of the diseases to which childhood is subject, but would also guide us in the application of therapeutic measures. The statistics of growth, taken in connection with those of disease, might very possibly reveal unexpected relations between periods of slow and rapid growth, and the ages at which certain diseases most frequently occur.

He referred to Dr. Percy Boulton's expression of "danger signal" in his paper on the weighing of children. Dr. Bowditch then exhibited a chart representing the case of a child, between two and three years old, where careful and systematic weekly weighing showed, first, the approach, by some weeks, of a chronic disturbance of nutrition, represented by enlarged cervical glands and clay-colored stools, and second, after recovery, the approach of an attack of measles, the "danger signal" of progressive loss of weight preceding the eruption by at least a week.

Dr. Billings spoke of the value of Dr. Bowditch's paper, and presented to the section the statistical cards intended for circulation by the National Board of Health.

Dr. Lee, of Baltimore, remarked that he had paid especial attention to this subject, and that he had noticed that a female child could lose more in proportion to its weight, without detriment to its health, than the male child of the same age. He also said that if the loss of weight preceding the eruptive disease was excessive, the case was so much the more grave in its prognosis, and that this loss of weight preceded the eruption by from four to five days.

Dr. Buscy, of Washington, read a paper entitled *The Relation of Meteorological Conditions to the Diarrhoeal Diseases of Children*.

INFANTILE ECZEMA.

Dr. White, of Boston, presented a paper entitled *Some of the Causes of Infantile Eczema, and the Importance of Mechanical Restraint in its Treatment*.

He first described the many and varied external influences which immediately affect the delicate skin of the new-born, as being a common cause of eczema, and laid especial stress on the fact that heat was the more usual cause of the disease than cold. He said, however, that these external influences furnish but a small proportion of all the cases of the disease which occurred at this period of life, although by far the greater part of those concerning the aetiology of which we have any positive knowledge. During the last twelve years he had treated at the Massachusetts General Hospital 5,000 cases of eczema, of which 1770 occurred in children of ten years of age and under, and of which the largest proportion, namely, 569 cases, was in the first year of life. He said, eliminating the operation of the causes directly acting upon the skin from without,

above mentioned, and a few other extraneous agencies, the parasitic chiefly, that he did not hesitate to say that he knew nothing whatever of the causes of the disease in the remainder; also, that as far as his experience went, eczema affected all classes of society alike, occurred at all seasons of the year, came in children of all degrees of health, in the perfectly sound as frequently as in the feeble; that it had no necessary connection with any other disease of childhood; that it showed itself in an equal proportion in bottle babies and those reared at the breast, and was independent of diet; also, that if there were other assigned causes, he would here say that his observation gave him no justification for believing any of them.

He stated that there was no more necessity for a supposed sympathy with or dependence upon the state of the blood, or the condition of some other organ, when the skin is affected with eczema, than when the lung, kidney, etc., is affected. He then, after speaking of the extreme suffering which the little patients undergo, said that the prime factor of the treatment was the prevention of scratching, and he described what he considered to be the proper method of controlling the child's movements, namely, a system of swathing in a pillow-case, by which the same chances of success in the therapeutics of infantile eczema was given, as existed in the adult.

He finally said that when the strait-jacket treatment is carried out, the child soon becomes used to the confinement, and a wonderful improvement takes place, not only in the disease itself, but in the *morale* of the family, which always becomes painfully disorganized during the existence of the disease; and he mentioned, as an important factor in the success of the treatment, that a grandmother (if present) in every case of infantile eczema, is the first evil to be eliminated. In conclusion, he considered that the simple mechanical means found in every household included all that was important in the treatment of one of the most distressing and rebellious diseases of infancy.

Dr. L. Duncan Bulkley, of New York, regretted criticising the paper as he felt obliged to do, in the absence of his friend Dr. White, but the views presented differed so radically from those which he had formed from experience that he could not help so doing, because he felt that the subject demanded it. For those who did not know of his acquaintance with the disease, he would state that he had recently made analyses of 2500 personal cases of eczema, and of these nearly 700 had occurred at an age which classed them as infantile eczema; he therefore believed that he could speak with authority on the subject. Dr. White had, it is true, treated of only one feature in the management of the disease, namely, physical restraint, but he believed criticism to be called for because of the principles which underlie, or which call for this element of treatment; the premises being wrong, what follows must of necessity be wrong.

The speaker believed that Dr. White here, as elsewhere, laid far too great stress upon local causes of eczema, and ignored entirely the influence of internal, general, dietary, and hygienic causes; if these are not recognized and managed, the results of local treatment are imperfect and uncertain. He did not believe that the children with infantile eczema were really in perfect health, but that always the evidences of imperfect assimilation could be discovered; the evacuations from the bowels were faulty, the urine constantly presented

evidences of mal-assimilation, and searching investigation would always demonstrate imperfect health in the child. In nursing children, the mother should always receive very careful attention, as very commonly she would exhibit dyspepsia, or constipation, or perhaps was taking ale, beer, much tea, etc., which disagree and cause trouble in the child; or perhaps she was very much debilitated, etc.

This subject could not be fully entered into here; the speaker expected to read a paper, on Diet and Hygiene of Eczema, before another section at the present meeting. He was, however, absolutely convinced of the importance of this matter, and that if attention was thoroughly paid to it much less would be required locally, and what was used would be more rapidly and completely successful.

Internal treatment to a certain degree was also absolutely necessary, and without it, physical restraint, as any local treatment, would be comparatively ineffective. This could not be discussed here, but he would only mention in illustration the internal use of small purgative doses of calomel, every other day, and a mild alkali, as acetate of potassa in the liquor ammoniac acetatis, with a little nitre and perhaps aconite. Individual cases required very different management.

In regard to the method of restraint proposed in the paper, he would say that he had never employed such restraint, simply because he had never found it necessary. If the itching was relieved, the restraint was not required, because the habit of scratching was soon overcome when the infant found that a proper application gave relief. If the itching is not relieved, such confinement was torture beyond any description, judging from the statements of older patients, who cannot abstain from it by any force of will, and who assert that they would scratch even if they died from it. The agony of little ones mechanically restrained was fearful to see.

In the paper the writer had mentioned the use of diachylon ointment. This the speaker very rarely employed in infantile eczema, as he believed it very inefficient in arresting itching. Tar in some form was far more efficacious; indeed, the speaker said that he had little to desire in the way of an application to infantile eczema beyond the following ointment: Recipe, unguenti picis, one ounce; zinc oxid, two drachms; unguenti alicis rose, three ounces. Mix. This should be very carefully prepared and very thoroughly and abundantly applied. If it appears stimulating, less of the tar ointment may be used. He laid great stress upon employing the rose ointment and not simple cerate, or lard, or vaseline, or petroleum. The ointment should be made of a consistency to spread easily and yet not to all melt away after application.

The writer had spoken of removing the restraining bands in order to wash the surface. The speaker was very positive in the directions given in regard to the use of water to eczematous surfaces in children; they were only to be washed according to direction, and that very rarely, often only at intervals of several days; moreover, it was all important that the protective ointment should be replaced *immediately* after the surface is dried, and renewed sufficiently often to keep the parts completely protected, even twenty or more times the first day. On covered parts the ointment may be thickly spread on the woolly side of sheet lint and bound on. Among hundreds of cases the speaker had never covered the face with a mask, and had rarely been obliged to return the infant much after the first day

or so. The only restraint he had ever practised was putting on muslin mittens, tied around the wrist, and then tapes from these passed behind the back or beneath one leg.

Under the management thus briefly indicated, if every point could be carried out, there was but one result, arrest of the eruption, and if dietary and hygienic elements were persisted in, a cure of the disease. The attention to the mothers of nursing children he considered most important.

Dr. Ulrich, of Pennsylvania, in discussing the paper, said that he fully agreed with Dr. Bulkley, and that he entirely opposed Dr. White's treatment. In a long professional career he had never used a system of restraint in these cases, and that he would prefer to knock the little patient on the head at once rather than submit it to the tortures of Dr. White's strait-jacket.

Dr. Jacobi said, in regard to the discussion on eczema, that there did not appear to him to be such a great difference between Dr. White's and Dr. Bulkley's views concerning restraint. For Dr. Bulkley admitted that the tying of the wrists was sometimes necessary. He (Dr. J.) had sometimes resorted to it, and also to the use of the mask. The local treatment of chronic cases consisted, first, in the removal of the scabs. Poulitice, oil, soap sufficed in mild cases; bad ones required the application, two to four times a day, of one part of liquor of caustic potash in eight to twelve parts of olive or cod-liver oil. In a few days the scabs can then be removed. Second, the soaking up of the oozing serum. Third, the use of astringents. The best of these is Hebra's diachylon ointment. Water is to be avoided, according to Hebra. Constitutional treatment directed against the eczema proper he knows none, except arsenic in protracted cases sometimes. Ill health has its own general indications.

THUMB-SUCKING.

Dr. D. H. Goodwillie, of New York, read a paper on Thumb-sucking, which he illustrated by the report of a case and exhibition of a wax model. The treatment consisted in breaking up the habit by applying a leather pad to the elbow, preventing the hand from coming to the mouth.

His conclusions were as follows:—

(1.) Thumb sucking is more disastrous to the health of the child than the sucking of the other fingers, for the thumb once in the mouth, it more readily remains there during sleep.

(2.) It interferes with the child's proper rest, which should be continuous, and undisturbed, and so becomes a source of nervous irritation and exhaustion.

(3.) It interferes with the natural respiration through the nose, and sets up abnormal conditions.

(4.) It malforms the anterior part of the mouth and affects proper mastication.

DIPHTHERIA.

MAY 5th. Dr. R. J. Nunn, of Savannah, presented a paper entitled Suggestions Touching the Treatment of Diphtheria. Dr. Nunn said that the disease had raged in Savannah with very fatal effects, and a letter from a friend elsewhere said that after treating 600 or 700 cases his faith in the efficacy of drugs was very feeble. The causes will probably remain speculative for a long time. Is the disease the same always and everywhere? The causative influences are probably not the same in

all cases. Medicines which cure the disease in Germany fail in this country, and the discussions as to the identity of croup, diphtheria, and scarlet fever are strong arguments in favor of this belief, and all treatment based upon one cause must fail to relieve all cases. Dr. Nunn quoted Dr. Jacobi as saying: "The entrance of the diphtheritic poison into the system is not the same in all cases. . . . There are cases in which the origin of the disease is decidedly local. . . . There are others in which the poisoning of the blood through inhalation is the first step in the development of the disease." A powder used by Dr. J. B. Read is as follows: Sulphur sub., grs. xlvij.; acid tannic, grs. xij.; acid salicylic, gr. i.; pulv. potass. chlor., grs. xij. Precaution must be used in compounding this prescription. A little of this powder is put on the back of the tongue every hour or two, and a small piece of ice given afterwards. It will be seen that this prescription is a combination of antiseptics principally.

In another case treated by Dr. Nunn, the following formula was used with good effect: Sulphur, grs. viij.; acid boric, grs. iv.; acid tannic, gr. i.; acid salicylic, gr. i.; resorcin, gr. i. Another formula is: Sulphur sub., grs. viij.; acid boric, grs. iv.; acid benzoic, gr. i.; acid salicylic, gr. i.; acid tannic, gr. i.; acid tartaric, grs. iv.; sodii chlorid., grs. iv.; resorcin, gr. i.

Dr. Lathrop, of New Hampshire, said he had experimented with chloroform largely, and found it a highly useful agent. He used it in diphtheria and other throat affections on a piece of cotton attached to a tube or pen-holder. The cases usually required visiting no longer than four days, but the cases were not so malignant as had been reported in other localities.

Dr. Lathrop stated that no unpleasant effects had ever followed this plan of treatment, and that the child, in true diphtheria, would not complain of *smarting* from the application of chloroform.

In regard to treatment Dr. Jacobi spoke as follows:—

Another remedy warmly recommended for diphtheria in the course of the last six months is pilocarpin muriate. Its prophet is G. Guttman. It is perhaps interesting to know that this is the first time his name comes before the professional public. It is equally interesting to learn that pilocarpin muriate, as recommended by him, is certain, very active, a quick remedy, superior to every other by which it has been preceded, and very probably also superior to every future remedy, and it is a specific. It is also important to know that this writer claims to have treated eighty-one cases of diphtheria in the course of a few months, all in the same manner; that twenty-two of these were very severe, and exhibited the most threatening and serious symptoms,—without, however, stating which they were,—and that he finally claims to have cured them in from one to five days, only two cases requiring nine and eleven days, and that there was *no failure*. The prescription for children was:—

R̄	Pilocarpin muriate	2 to 4 centigrammes.	
	Pepsine	60 to 80 "	
	Acid. muriat. dil.	gtts. ij.	
	Aque	80 grammes.	M.

S. A teaspoonful every hour day and night.

For adults he writes:—

R̄	Pilocarpin muriate.	3 to 5 centigrammes.	
	Pepsine	2 grammes.	
	Acid. muriat. dil.	gtts. ij.	
	Aque	240 grammes.	M.

S. A tablespoonful every hour day and night.

A tablespoonful for adults and a teaspoonful for children of Hungarian wine was given after each dose. Cold applications were made to the throat every eight hours. Warm milk, coffee, or soup were given every two hours. Plenty of cold water or small pieces of ice were allowed.

Without regard to this plan of treatment, I wish to add that before Guttman, Lehweiss, in St. Petersburg, reported several favorable results obtained in diphtheria by the subcutaneous injection of pilocarpin muriate. The following remark may not be out of place. The manner in which the remedy is proclaimed by Guttman, as an infallible specific, the invariably good results which have been reported to have taken place reminds us of nothing more nor less than the verbose and reckless manner in which professional quacks advertise their nostrums. The action of pilocarpin is well known. It increases the secretion from all the integuments, skin as well as mucous membrane. The effect claimed for the remedy is that by increasing the secretion it will remove the macerated membranes, and thus relieve the diseased surface. Now, diphtheritic membranes are of two kinds. They are either deposited upon the mucous membrane or they are imbedded in the mucous membrane and submucous tissue. It is easily understood how a mucous membrane may throw off a diphtheritic membrane which has been deposited *upon* it, but it is not so readily understood how a membrane embedded *in* the mucous membrane and submucous tissue can be easily macerated, and cast off in the same manner. Those cases in which there are only membranes deposited upon the surface are apt to recover under the influence of any treatment. In fact, a number of them will do quite well without treatment. But those severe cases in which the mucous membrane and the submucous tissue are the seat of a necrotic process, are of a different character. They are generally of a septic nature, and are not so apt to heal by simply removing the diphtheritic deposit.

The efficacy of a new remedy must be tried, not in moderate but in severe cases, and for that very reason I have personally used pilocarpin muriate in severe cases, in cases of nasal diphtheria, and in the septic form of pharyngeal diphtheria, with or without glandular swelling. In not a single case have I seen the slightest favorable effect, but, on the contrary, I feel sure, from two or three observations, that the fatal termination was certainly accelerated by the influence of the remedy. So far as we know to this day pilocarpin, either directly or indirectly (by producing vomiting), debilitates the heart's action to a great extent, and where the pulse is frequent and small, the action of the heart feeble, and the tendency to collapse prevalent, as in many cases of serious diphtheritic affection, pilocarpin muriate can do no good. For this reason the few cases published by a few writers in our own midst prove, in my opinion, absolutely nothing. There is not a single one of all the vast number of antidiphtheritic remedies during the administration of which patients would not get well. A number of European writers, for instance, Hensch, Neumeister, R. Weiss, have published a number of cases in which the remedy administered conscientiously proved to be either useless or injurious.

CLUB-FOOT.

Dr. E. H. Bradford presented a paper entitled Resection of the Tarsus in Severe Cases of Club-Foot, of which the following is a summary:—

Dr. Bradford first reviewed the literature of the subject, and then reported two cases on which he had operated.

The first case was a girl eleven years old, with severe equino varus, the axes of the foot being at right angles with that of the leg.

Tenotomy and mechanical treatment were tried for a month with but slight benefit. Dr. Bradford removed a wedge-shaped section of bone from the tarsus with a metacarpal saw, and, with antiseptic precautions, there were no constitutional symptoms after the operation, excepting that the temperature rose once to 101° F., being otherwise normal during the recovery. The wound healed under the blood clot as occurs with a thorough antiseptic dressing, and in five weeks the patient was able to walk without a cane. She remained in the hospital for some time under observation, and was discharged with the foot nearly in a normal position.

The second case was a boy, thirteen years old, with double congenital club-foot of aggravated type. The first foot was operated on November 9th, and was sufficiently well to bear his weight by December 12th, and was entirely healed by January 19th. The second operation was performed January 9th, and by February 14th he was allowed to walk on both feet. He remained under observation until April 24, when he could walk a mile without apparatus and wearing ordinary shoes. The temperature rose to 102° F. on the second day of the first operation, but fell to the normal on the next day, and remained so. After the second operation, on the third day the temperature rose to 101° F., but fell after removing the drainage tube, which was stopped, and there was no subsequent rise. The plaster-of-Paris bandage was made use of after the operation. Dr. Bradford then described minutely the after-treatment in this case, and stated that there remained, after recovery, about thirty degrees of motion, and that the boy could stand on either foot, or raise himself on his toes.

In regard to the antiseptic precautions, Dr. Bradford thought that they offered the best safeguard, and that it must be admitted that a study of the reported cases justifies the impression that the danger is not so great as has been supposed.

The temperature charts, the photograph, a tracing of the left foot, and a cast of the right foot before and after operation of the second case were exhibited.

Dr. Jacobi remarked that Dr. Bradford's cases were exceedingly interesting and instructive, and said that, as shown by the casts, they could not have been successfully treated without just such a procedure as Dr. Bradford had adopted.

MIDDLE-EAR DISEASE IN ACUTE EXANTHEMATA.

MAY 6th. Dr. C. J. Blake, of Boston, presented a paper entitled Middle Ear Disease in Children in the Course of the Acute Exanthemata.

Dr. Blake first spoke of the frequency of the disease, as shown by the facts that 35.70 of all the cases of purulent inflammation of the middle ear occurring at the Massachusetts Charitable Eye and Ear Infirmary followed measles and scarlet fever, and of deaf-mutes examined by the writer, 27.70 lost their hearing as the result of scarlet fever.

In both exanthemata the inflammation affects the mucous membrane lining the middle ear, occurs during the acute stages of the primary disease, and runs its

course quickly; hence its importance to those having to deal with diseases of children.

Dr. Blake then said that much might be done in the early stages to diminish the severity and shorten the duration of the inflammatory process, which in children, owing to the greater vascularity of the mucous membrane, and the readier solution of continuity of the tissues, favoring ulceration, is usually more rapid than in adults.

In scarlet fever, the aural complication may occur at any time; usually runs its course rapidly, and furnishes in a short time a well-marked acute purulent inflammation of the middle ear.

In measles there are two types, one occurring early and corresponding to the acute catarrhal inflammations following "head-colds;" the other originating primarily in the membrana tympani, and accompanying the appearance of the facial eruption. The symptoms in that form occurring during scarlet fever, are rise in temperature, pain at first occasionally, then constant, in very young children, shown by moaning, unrest, and a desire to press the affected ear against the pillow. These symptoms are of course due to increased pressure within the tympanic cavity from serous exudation, as is shown by the relief afforded by the use of the Politzer and douche, permitting the escape of a part of the fluid. The continuous pain later is often not similarly relieved, either because of serous effusion of the membrane itself, or more complete closure of the Eustachian tube.

Nature usually relieves the pressure by a spontaneous opening, but only after prolonged suffering and prostration on the part of the patient, or possibly serious injury to the transmitting structure of the middle ear. The opiate treatment is superficial. In the early stages, frequent gargling, and if pain is complained of, the air douche should be used frequently. Instillations of warm oils and poultices are objectionable, as they interfere with subsequent operative interference; if necessary glycerine and warm water, two or three parts to one, and a dry cloth over the ear are better.

In a later stage, if pus is present, the evident remedy is puncture of the membrane at its most prominent portion with a lance, suture needle, or saddler's needle.

Dr. Blake then spoke of measles. In the first form the remedies referred to in the early stages of scarlet fever are equally applicable here; if they fail, acupuncture and drainage are preferable to paracentesis, which may be done with a needle, and then a wick inserted, which serves the double purpose of withdrawing the serous fluid, and keeping the lining of the canal dry. Syringing should only be resorted to when the discharge becomes muco-purulent.

The second rare form is characterized primarily by a congestion of the membrana tympani, without congestion of the tympanic mucous membrane, and is not relieved by the use of the air douche. It is due probably to inhibition of the vaso-motor nerves controlling the tympanic branch of the carotid artery.

These cases either resolve spontaneously, or the conditions described in the first type of inflammation of the middle ear becomes established. Instillation, dry warmth and acupuncture, may be resorted to with good effect. For general treatment the bromides are especially indicated.

Dr. Jacobi remarked that closing the mouths of infants and children, and simply blowing into the nose, is often a very valuable method of relieving severe earache, and that in a number of cases he had obtained

most excellent results from this procedure, the cause of the trouble probably being a catarrhal affection of the Eustachian tube.

PROGRESS IN THE KNOWLEDGE OF THE ACUTE CONTAGIOUS DISEASES AND INFECTIONS.

Dr. Jacobi remarked that his paper should have been read before the general session, but that on account of the crowding of business on the last day he would read the paper to the section. He said that the Children's Section was a new one; that he was anxious to see it a prosperous and interesting one, and that the sympathy and coöperation of the gentlemen were necessary to its success. He then spoke as follows:—

"The limited time at my disposal precludes my going over much ground. The remarks I shall give will, therefore, be confined to the progress made in our knowledge of the acute contagious constitutional diseases (rubeola, scarlatina, variola, and typhoid fever), and the acute contagious infections of the mucous membranes, such as dysentery and diphtheria."

The literature of the subject during the past year was given, embracing text-books, atlases, and monographs, which were exhibited before the section.

The concluding words of Dr. Jacobi on rubeola are as follows: "Evidently the latest contributions to our knowledge of rubeola give weight to its classification amongst the acute contagious constitutional affections." . . . "The description of the symptoms varies a good deal with the authors. These differences are best explained by the fact that mild cases of either measles or scarlatina may not present all their usual symptoms, and by the other fact that during the prevalence of an epidemic of rubeola there is, as a rule, a contemporaneous epidemic of measles and scarlatina, and also diphtheria."

In such times cases of common nasal, pharyngeal, and laryngo-tracheal catarrh are very frequent indeed; thus there have been but very few infants and children in our large northern cities but were affected in this manner. Thus it happens that there are many symptoms belonging to the mucous membrane of the digestive and respiratory tract which invariably complicate the slightest other affections. Thus it is, also, that many authors have looked upon these accidental complications as if they were genuine symptoms. The very best authors, — for instance, Gerhardt, — when they mean to describe rubeola depict mild or sometimes even single cases of measles. Nasal catarrh, conjunctivitis, facial œdema, glandular swellings belong to this class of symptoms, which, while they often occur in rubeola, do not belong to it by any means. The disease is very contagious. Its incubation lasts from two to three weeks, and is not attended with any fever. Now and then there are, during a period from twelve hours to two or three days, prodromata, a mild increase of temperature, sometimes a catarrh of the mouth. The tongue is apt to show a few red marks along the margin, mainly in its anterior portion. The eruption, according to what I have seen, does not — contrary to Gerhardt's observations — begin in the face, but on the trunk or more frequently on the extremities, mostly on the thighs and knees. Head and feet are not often affected. It looks very much like that of measles, sometimes not rising above the level of the skin, sometimes, however, rising above it in the manner of an urticaria. It seldom lasts longer than three days, but relapses on the fourth or fifth day are frequent. Desquamation begins early,

now and then on the third or fourth day. Relapses may take place while desquamation is undisturbed in some localities. The temperature seldom exceeds 102° or 103° F.; becomes normal about the fourth day. The prognosis is absolutely good, and the treatment either none at all, or expectant. The diagnosis, however, may be very difficult, and even impossible in an individual case, inasmuch as scarlatina, and particularly measles, are apt to be rife at the very periods of the rubeola epidemic, and their symptoms are complications too mild to be estimated at their full value. This fact, however, does not militate against the independent nature of rubeola, for it has never been claimed that either measles or scarlatina can and must be recognized in every instance."

Speaking of *diphtheria*, Dr. Jacobi said: "In this connection I desire to say a final word in regard to large doses of chlorate of potassium, often recommended in diphtheria. My warning in regard to this drug has at last been heeded. Extracts from my writings on this subject have been extensively published, and experiments on animals made in Europe by Marchand and others have proved my clinical observation of the frequent occurrence of nephritis, and fatal nephritis, resulting from the incautious use of the potassium chlorate. A number of fatal cases have been described, and it may be that much carelessness on the part of the public and many accidents will be avoided in future."

In the article on *typhoid fever* the same writer says: "With reference to the effect of the bathing in typhoid fever he appears to have made the same observations detailed by myself some years ago in a lecture on typhoid fever published in the *Medical Record* of 1879. Whenever circulation is deficient, particularly when the patients have been anæmic at the onset of the disease, whenever, after the cool bathing, the feet do not get warm as quickly as the rest of the body, the end for which the bath was given is not attained. In order to reduce the temperature of the body permanently it is necessary that the circulation of the skin be restored very soon, and uniformly. If such be not the case no radiation from the external surface of the body can take place, and an undue amount of heat is retained within the body. It may then occur that the surface is quite cool while the temperature in the rectum is very high. In such cases, in order to reduce the temperature, I have had to plunge the patient into hot water for the purpose of restoring the cutaneous circulation. When, in such patients, cold water is to be used, the only proper mode of applying it is by packing or sponging. In these cases care must be taken that only the trunk and the head are made the subject of local treatment."

Dr. Leigh, of Petersburg, reported two fatal cases of poisoning from chlorate of potash. The first was the case of a child three years of age with diphtheria. The mother gave the child one-half ounce of chlorate of potash, and the child died within 24 hours.

The second case was a child five years of age with croup. It took 6 drachms of chlorate of potash in 24 hours; cyanosis appeared in six hours; hæmaturia and death in 48 hours.

Dr. Potter remarked that in quite a large number of cases in his practice he had met rubeola and diphtheria occurring together.

Dr. Jacobi said that he had no doubt but that a number of deaths had occurred from chlorate of potash. When the blood is examined the corpuscles are

broken up and irregular, and there is a conglomeration of hæmatin scattered about. There is no positive poisonous dose: $3\frac{1}{2}$ drachms given for 5 or 6 days killed a robust boy of 14 years. Dr. Jacobi had taken himself half an ounce, and this dose was followed by frequent micturition.

Dr. Fontaine, a friend of his, however, took one ounce with fatal result.

In answer to a question as to whether measles ever occurred twice in the same person, Dr. Rotch stated that during the epidemic which had lately been prevailing in Boston the disease (measles) had been observed to occur not only twice, but three times in the same person.

Dr. Selden, of Norfolk, in a long professional career, had never seen measles occur twice.

Dr. Lee, of Baltimore, expressed surprise at Dr. Rotch's statement, and said that in his opinion true measles never occurred twice, and that where a second attack was apparently present, close investigation showed that it was the diagnosis which was at fault, and that the eruption, although simulating that of measles, was really that of the roseola spoken of by Dr. Jacobi in his paper; he also inquired of Dr. Rotch whether he could distinguish the eruption of measles from that of roseola, and from the eruption which apparently followed certain articles of diet, as crabs?

Dr. Rotch answered that he would first say, in order that there should be no confusion of terms, that there was a true measles and a rubella (the röteln of the German writers), as stated by Dr. Jacobi, and that so far as the eruption was concerned it was often impossible to make a distinction between the two; second, that roseola had nothing to do with the other diseases, and that in the great majority of cases the eruption caused by eating crabs was that of urticaria, which of course was easily distinguished from the eruption of measles; third, that he would again state that undoubted cases of a second attack of true measles had been observed in Boston, where the disease rubella is well-recognized and differentiated from measles.

In the recurrent cases to which he referred, Dr. Rotch said that reliance was not placed on the eruption alone, but on the general course of the disease, namely, a regular prodromal stage with coryza, conjunctivitis, and bronchial catarrh followed by a characteristic eruption and a stage of desquamation, and that as these cases had been met with and reported by competent observers, there was no more reason why they should not be called a second attack of measles than when the same symptoms occurred in a patient for the first time.

Dr. Atkinson, of Baltimore, said he had undoubtedly seen numerous cases of recurrent measles.

Dr. Stiles, of New York, had seen cases where true measles had attacked the same children twice.

Dr. McDonald considered that the cases spoken of by Dr. Stiles were merely relapses of the original disease.

Dr. Jacobi agreed with Dr. Rotch that the term rubella should be used for this disease, which simulates measles, roseola being something different, as in typhoid fever.

He then said that he had frequently seen cases where what he considered the symptoms of true measles had occurred, and an exact recurrence of these symptoms years afterwards, and that he called the second attack true measles, and considered that measles could occur two, three, or four times; and he would beg leave to

repeat the old story: "It eats like a toad, it looks like a toad, it creeps like a toad, hence why not call it a toad."

Dr. Adams, in referring to Dr. Jacobi's remarks regarding the great contagiousness of measles, described the admirable method of isolation employed in these cases in the Children's Hospital in Washington.

V. OBSTETRICS AND DISEASES OF WOMEN.—Chairman, Dr. James R. Chadwick, of Boston; Secretary, Dr. Joseph T. Johnson, District of Columbia.

Dr. Paul F. Mundé, of New York, read a résumé of rules for the use of pessaries, summing up under twenty headings a recapitulation of the rules which should govern their introduction and supervision.

Dr. R. Beverly Cole, of California, spoke after Dr. Mundé. He said the Hodge pessary was the first one invented which showed any knowledge of the anatomy of the female organs. No two pessaries were exactly alike. Dr. Albert H. Smith, of Philadelphia, had constructed one which had the peculiarity of Simpson's (also Hodge's) hard rubber instrument. He then exhibited his pessary with the important modification of a spring support for retroversion. The great advantage claimed by Dr. Cole for this modification over others for this class of cases (retroversion) is that there is no risk of inflammation from the uterus having to impinge, during the various movements of the person, upon a rigid, unyielding point.

Dr. Chadwick next made the discussion general, and called upon Dr. Smith, of Philadelphia, who said that, in his opinion, pessaries were too much used, as they were often hurtful if not used judiciously. He said his pessary was only intended for retroversion and prolapsus. Anteversion, antelexion, and retroversion he had frequently relieved by means of the intra-uterine stem pessary, but he did not believe in the galvanic action. He thought it simply mechanical.

Dr. H. P. C. Wilson, of Baltimore, Md., agreed with Dr. Mundé, of New York, as regards the importance of ascertaining whether the uterus can be lifted up before introducing any pessary. He said he was often compelled to use a dozen or more before he could get one to fit with comfort. He remarked that he had once succeeded in relieving a case of antelexion by introducing Hodge's horse-shoe pessary. Dr. Wilson did not approve of stem pessaries. He said he had the best results in antelexion from splitting the cervix backwards and the os internum backwards and forwards.

Dr. Maughs, of St. Louis, discussed the ligamentous supports of the uterus, and dilated upon the importance of the vaginal walls and perineum as supports. He said that, in his opinion, stem pessaries had killed hundreds of women. He said anterior displacements were the rule in virgins, posterior in multipara.

Dr. Quimby, of Jersey City, said he had never derived any satisfaction from the use of stem pessaries, and that he is more and more inclined to avoid the use of all pessaries as he grows older.

Dr. Mundé was requested by the chair (Dr. Chadwick, of Boston) to close the discussion, and rose to make some explanations, and was followed by Dr. R. Beverly Cole in a few closing remarks.

—A death certificate received at the Chicago Health Commissioner's office gave "colera" as a cause of death in a child.

Medical and Surgical Journal.

THURSDAY, MAY 19, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

NO. 4 PARK STREET, BOSTON, MASS.

THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

THE late meeting of the American Medical Association at Richmond was, it seems to be generally agreed, from a social point of view, eminently successful.

The proverbial southern hospitality, a hospitality which in former times was nowhere more profuse and kindly than in old Virginia, was fully equal to the occasion, and, although the number of members attending, between five and six hundred, — of whom Massachusetts contributed about forty, — was not so large as had been anticipated, and especially less large from certain States which had been expected to send full delegations, still there were quite enough to put the friendly offices of the citizens of Richmond to a good test, and if the hosts experienced any disappointment as to the severity of the test, this must have been amply offset by the genuine and hearty appreciation of the kindnesses and civilities extended.

From a scientific point of view the best that can be said of the meeting is that it was certainly not superior to the average of its predecessors. As a rule the discussions in the sections were tolerably trivial, and their value and interest is in no way increased by the reëxhibition of apparatus, such as the plaster-of-Paris jacket, already pretty generally known, and of various new-fangled or newly modified instruments, most of which probably never will be known outside of the inventor's practice. We had certainly hoped that no new pessary would make its appearance. The addresses were on a much higher level than the discussions, and several of them, notably those of the president, of Dr. Pepper in the Medical and of Dr. Chadwick in the Obstetrical and Gynecological sections deserve careful perusal. If any of the sections are to be excepted from the previous remarks, those for the Diseases of Children and for the Practice of Medicine might be. An energetic chairman and an active secretary can do much, unquestionably, toward adding interest to the proceedings of the section under their care.

The question of admitting homœopathic students to the courses at regular schools, which has been a burning one for several years, was finally disposed of by a compromise. The homœopath is to be allowed an education but not a diploma. This conclusion was not arrived at without affording an opportunity for some very animated and eloquent debate, in which the rhetorical honors were somewhat evenly divided, though

we have been assured by one of the audience, not long back from France, that the oratorical prowess of the persuasive professor from Chicago he had never seen matched unless by the efforts of Gambetta.

The question suggested last year by Dr. Sayre, of the Association's starting its own journal, in which the papers submitted might receive prompt publication, was again brought up and referred to a committee of five, to which the secretary and treasurer were subsequently added. It seems probable that by another year this proposition will take some definite shape. The name of an editor is already suggested. The advantages to the Association of such a publication are obvious. Prompt publication will secure better papers, and better papers will incite to more interesting discussions. The choice of Dr. Woodward for President of the Association, gave great and general satisfaction.

The Association is to meet next year at St. Paul, Minnesota, and it is said that Boston is mentioned as a proper place for an early meeting.

MEDICAL NOTES.

— The Massachusetts Senate refused by a vote of nine to fifteen to reconsider the vote by which the bill to establish boards of visiting physicians for the state lunatic hospitals was refused a third reading.

— A case of small-pox has been discovered in Cambridge, the origin of which could not be traced.

— New York reports 822 deaths for the week ending May 14th, the largest number yet. Of these 19 were from small-pox, and 9 from typhus fever.

— Surgeon John S. Billings, United States Army, has been detailed to proceed to London as a delegate to the International Medical Congress next August.

— The students of Trinity College, Hartford, have been dismissed for three weeks on account of a case of varioloid.

— Another serious outbreak of scarlatina at Halifax has been traced to a polluted milk-supply. Of eighty-two families supplied by a particular milkman, forty-five were attacked by the epidemic. It was subsequently ascertained that the man had five children ill of scarlatina at the time he was supplying these families, and he was thus spreading disease and death broadcast amongst his customers. If conduct of this description is not criminal, and punishable accordingly, ought not the legislature to step in at once to protect the public by imposing some severe penalty for offenses of such a nature?

— The ham fair annually held at Paris, in the neighborhood of the Bastille, has lately closed. The examination of the hams and sausages offered for sale during the fair is most reassuring for the Parisian public, and a convincing proof of the efficacy of the measures adopted to prevent trichinosed ham from becoming an article of commerce among the Parisian pork-butchers. In the 266,100 pounds of ham sold at the fair, not one joint was seized. Moreover, not a single sausage was condemned. Trichinosis was conspicuous by its absence; but 4500 pounds of meat was destroyed, being unfit for human food.

—Malarial affections in Connecticut are reported to the State Board of Health as maintaining about the same position as of late years. In some places they are stated to be increasing in frequency, and the severer types becoming more frequent or appearing for the first time. No new regions are reported, although some of the physicians in several towns in Windham County consider the symptoms that appear very like those elsewhere ascribed to malaria, and find quinine unusually effectual.

NEW YORK.

—At the last meeting of the Medico-Legal Society, May 4th, which, it was announced, was to be devoted to a discussion of Dr. Hammond's paper on the medico-legal relations of Syggnoscism, or Hypnotism, read at the April meeting, Dr. Beard delivered a long address, in which he repeated much of what he said in his recent paper on Mesmeric Trance before the Academy of Sciences. He contended, however, that Dr. Hammond's theory of suspension of function in the superior and median tracts of the brain was as erroneous as the German idea that the function of one hemisphere was suspended in hypnotism. As to the medico-legal relations of trance, he stated that he did not believe it to be at all necessary to change the criminal law on account of this psychological peculiarity; but he did anticipate that, in the light of present and future developments concerning the subject, the law of evidence would have to be reconstructed. During the course of his remarks he made some interesting experiments with subjects, which were of the same general character as those of Dr. Hammond at the preceding meeting.

—The city is passing through its annual excitement in regard to the healthfulness of Croton water. At this season there is very apt to be a little unpleasant taste in the water, and this year it happens to be somewhat more pronounced than usual, although there is a great difference in this respect in the water in different sections of the city. There is no doubt that measures will before long have to be taken to increase the supply of Croton; but in the meanwhile the officials in charge of the water department are using every possible precaution to keep the water pure, and there is every reason to believe that the slight disagreeable taste which it has is only a temporary condition, and one which has not the slightest deleterious effect upon the public health. Professor Chandler, the president of the Board of Health, who for the past twenty years has made the subject of water-supply a special study, and for sixteen years has paid particular attention to the quality of Croton water, officially asserts that there is no reason whatever to apprehend any injury to health from drinking the water in its present condition. He deprecates the sensational statements that are being made in regard to it as giving rise to unnecessary alarm, and points out that the water is drawn from an area of 340 square miles as free from all sources of pollution as any such area can be; hundreds of analyses, made from time to time, having shown that the Croton water is equal in purity

to the water-supply of any other large city in the world.

—As there have been of late a number of cases of vitriol throwing reported to the police of the various cities of the State, and the penalty for this vile offense has been heretofore altogether too light, the legislature has unanimously passed a special act making it a felony to throw vitriol or any corrosive substance, the punishment for which shall in the future be imprisonment for not less than two and not more than ten years.

—The death of a lady twenty-four years of age from lead-poisoning, the result of the immoderate use of cosmetics has just been reported.

—The first arrest under the new law relating to the registry of physicians took place on the 4th of May, the accused being Abraham E. Cox, who is charged with perjury in swearing that he graduated and received a diploma from the University of Castleton, Vermont. When arraigned in court he pleaded not guilty to the charge of perjury, and also accused an official in the county clerk's office of corruption, stating that he had paid the latter one hundred dollars to allow his name to be registered. There seems to be no ground whatever to suppose this charge to be true, since in order to register it is simply necessary to answer certain questions which, with the signature, are recorded in a book kept for the purpose. The law is designed to protect the public from impostors, and if the present energetic efforts of the County Medical Society to have it thoroughly enforced are crowned with success, the community will soon have the assurance that whenever a physician's sign is displayed it means that the practitioner has gone through a regular course of study in a reputable medical college.

—The profession has lost a valuable member in Dr. Salvatore Caro, who died on the 30th of April from cerebro-spinal meningitis. For a considerable time previous he had been suffering from severe nervous prostration, and it is said that this was induced by the worryment of mind incident to a long course of litigation which he had with the Elevated Railroad company on account of damage by the latter to some property of his in Fifty-Third Street, through which the road passes. He was born in Italy, and received his degree from the University of Palermo. For a number of years he had resided in New York, where he acquired a large practice, and where he was an active worker in all the principal medical societies.

—A certain New York physician who, having changed his office on the 1st of May, left a sign stating that he had removed to such a number in such a street, was somewhat startled to find that under the latter had been painted the words, "For which we are truly thankful." It seems that the landlord had not been on very good terms with his tenant, and had taken this singular means to revenge himself. The upshot of the matter was that the doctor had the landlord arrested, though the prisoner was soon discharged on condition that he would remove the obnoxious words.

—At a stated meeting of the Academy of Medicine, held May 5th, Dr. J. Lewis Smith, clinical professor of diseases of children in the Bellevue Medical College, read a paper on Pleurisy in Children.

—During the passage of the steamer *Assyrian Monarch*, which left London April 15th and arrived at New York April 28th, small-pox broke out among the steerage passengers, who were chiefly Polish and East German peasants, and of uncleanly habits. There were five persons ill with it (of whom one, a child fifteen months old, died in three days after being attacked), and by order of the captain they were separated from the rest of the passengers, and placed in a small compartment in the forward part of the vessel, where they were well cared for. As soon as the ship reached New York harbor Health Officer Smith sent the sick to the hospital on Blackwell's Island, and vaccinated the rest of the passengers, numbering about five hundred. A considerable number of the crew, however, refused to submit to vaccination, and by way of precaution were sent off to Hoffman's Island, to remain till all danger of infection should be passed. Not long before the steamer *Victoria* had also arrived from England with small-pox on board.

—A floating reception hospital for typhus-fever patients has been anchored in the East River off Bellevue Hospital, about one hundred feet from the shore. It is built on a scow, and contains two apartments, one for men and the other for women. The Board of Health provides a nurse to attend the patients while they remain, and the hospital steamer calls twice a day to remove patients to Blackwell's Island. The "Shiloh" lodging-house, in which the first cases of typhus appeared in New York, has been permanently closed by order of the Board of Health.

—A fatal case of what was reported by the physician in attendance to be relapsing fever has proved, on investigation by the health authorities, to be one of cerebro-spinal meningitis. It would not be surprising, however, if relapsing fever should make its appearance in the city, as this affection is very apt to be prevalent in connection with typhus fever. The latter has materially decreased within the last fortnight.

—The police commissioners, who for some time past have been on trial upon charges preferred by the mayor for neglect and fraud in cleaning the streets, have now been indicted by the grand jury, but the streets remain for the most part as filthy as ever.

PHILADELPHIA.

—The American Laryngological Association held its third annual meeting in this city on May 9th, 10th, and 11th. The papers, according to programme, were as follows: Annual Address by Dr. J. Solis Cohen, president of the Association; Lupus of the Pharynx and Larynx, by Dr. Asch; On Tubercular Ulceration of the Mouth, with a report of cases, Dr. Bosworth; The Relation of Hay Asthma and Nasal Catarrh, Dr. Daly; A Contribution to the Histology of the Thyroid Cartilage, by Dr. Elsberg; On the Operation for Deviation of the Nasal Septum, Dr. Glasgow; Lupus

Laryngis, Dr. Knight; The Question of Hæmorrhage after Tonsilotomy, Dr. Letterts; The Prognosis of Laryngeal Phthisis, Dr. Porter; The Laryngeal Affections of Pulmonary Phthisis; The Comparative Value of Atomized Fluids in the Treatment of Diseases of the Larynx, Dr. Roe; Paralysis of the Vocal Cords due to Lead Poisoning, Dr. Sajons; The Effect of the Condition of the Nasal Cavities upon Articulate Speech, Dr. Seiler; Certain Neuroses of the Throat, Dr. Smith; and one upon the question, Is the Brush, Sponge, etc., the most Rational Method of making Local Applications to the Mucous Membrane of the Superior part of the Respiratory Tract? Dr. Rumbold. A number of papers were also presented by candidates for membership upon allied topics, and referred to the committee. A special excursion to Atlantic City, and a reception by the Philadelphia Laryngological Society constituted the entertainments. The meetings were held in the hall of the College of Physicians, which had been kindly offered to the Association for the purpose.

—The Pennsylvania State Medical Society also held its annual session last week, meeting at Lancaster on Wednesday, May 11th, and continuing in session three days. A special report of this meeting will be found in an early issue of the *JOURNAL*.

—The Philadelphia County Medical Society is now in a thriving condition. Owing to the energy of its board of directors its bi-weekly meetings are well supplied with interesting material, and very often two papers are submitted for discussion upon the same evening, in addition to reports of cases, presentation of specimens, etc. At the last meeting, April 27th, the subject of Alcohol, by special resolution of the Society, was presented for discussion. Dr. Roberts Bartholow opened with a paper on the Therapeutics of Alcohol used Internally and Externally, followed by Dr. H. Lettman on the Medical Relations of the Commercial Adulterations of Wines and Liquors, and by Dr. H. C. Wood on the question, Is Alcohol a Food? When should Malt Liquors be preferred to Wines and Spirits in the Treatment of Disease? These topics were generally discussed subsequently by the members present, and, judging from the interest shown and the large attendance, this plan was a decided success. At the next meeting the discussion will be concluded by two papers, on The Use of Alcohol in Disease, by Dr. Wm. Pepper, and one on The Treatment of Alcoholism, by Dr. Jas. Hutchinson.

—The Episcopal Hospital has received for the establishment of a children's ward an endowment fund of seventy thousand dollars, and the work is being rapidly pushed forward; the new ward is expected to contain twenty-four beds, at least it is so stated in the public press.

—The Society for the Prevention of Cruelty to Children has presented a formal complaint against our almshouse, where it is asserted that there has been a mortality in the children's department of one hundred per cent.! No child left in the kind, maternal care of this model institution was ever known to grow up within its walls, the only chance of survival offered

was that of adoption by some charitably disposed person, and removal from the place. The grand jury, after investigating the case, found the facts to be as stated, which they attribute partly to the poor stock of babies sent to the hospital, which are mostly foundlings, secondly to the fact that the nursery is adjoining the surgical ward, and is badly ventilated, and thirdly to the neglect and incompetency of the pauper nurses employed to look after the children. The first-named society having offered to take care of the children, the court ordered their transfer accordingly, and all future foundlings will be placed in its care.

—The same grand jury also stated in their report that the continuous employment of conductors and drivers upon the street-cars for seventeen to eighteen hours a day, as they are at present required to work, was injurious to the public welfare, and condemned the car companies for their inhumanity.

—Among the interesting cases of recent occurrence may be mentioned two under the care of Dr. Thos. G. Morton. One was a successful removal of a large (three fourths pound) uric acid calculus from an old lady, seventy-nine years of age, by colpocystotomy, with a successful result, the other was a case of a young man suffering from old paralysis with atrophy of the legs, infantile in its origin, which completely prevented locomotion, and consigned the man to the poor-house. Dr. Morton, finding motion preserved in the thighs, strapped the legs to the thighs, and put on a pair of artificial legs, and the man was able to walk or run almost as well as any one, "he can run like a deer," as Dr. Morton said. These cases will probably be presented at the next meeting of the Academy of Surgery.

—At Jefferson College some important alterations have been authorized by the board of trustees. The front of the main hall is to be torn down, and the rooms enlarged, special attention being paid to ventilation. The dissecting-room is to be vacated, and converted into a laboratory, and a new dissecting-room built above the old one. Some minor changes in other departments will also be made, more especially will a room be devoted to therapeutical and physiological investigations under the direction of Professor Bartholow.

—A medical club was started at the first of the year in this city with a membership limited to one hundred; it has secured a very convenient house in the centre of the city, and promises to be very popular, especially among the younger members of the profession.

—A new medical society was organized here last month under the title of the West Philadelphia Medical Society, which is chiefly social in its objects.

—The medical profession of Philadelphia recently held a meeting under the auspices of the County Medical Society in favor of the establishment of a state Board of Health, and passed a series of resolutions, which were transmitted to the State Legislature. By the time this is received it is to be hoped that the bill now before the legislature for this purpose may become a law. Certainly the various medical societies have done all in their power to favor its adoption.

Miscellany.

LETTER FROM VIENNA.

EXTIRPATION OF THE STOMACH.

MR. EDITOR.—Since the publication of my letter to the JOURNAL describing the first successful extirpation of the pylorus, Professor Billroth has operated on two other cases in like manner, both with fatal results. Both patients were women of about forty years of age, with a history of disease of four and six months. In the first case the tumor was firmly adherent to the anterior abdominal wall and diaphragm, and the stomach was much dilated. After the removal of the tumor the gastric wound was united as in the first case, until an opening of sufficient size was left at the lesser curvature, and into this the duodenum was stitched. The result, as regards the shape of the stomach, was not as good as in the first case, there being a deep, angular pocket formed below the point of attachment of the duodenum. The operation lasted two hours and a half.

On the days following the operation the small amount of liquid nourishment given was all vomited, a symptom never present in the first case. This continued until the sixth day, when, the patient being greatly exhausted, Professor Billroth decided to reopen the abdomen, in the hope of relieving the obstruction to the passage of food that was believed to have formed. The stomach was found to be fixed to the old points of adhesion on the anterior abdominal wall and diaphragm, and to be folded on itself in such a manner as to close the opening into the duodenum. There was no peritonitis, and the gastric wound was entirely healed. The gastro-duodenal wound was partially reopened, and the edges stitched to the abdominal opening, in the hope of establishing a fistula, by means of which the patient might be fed. She never rallied, and died in thirty hours, of exhaustion.

The next patient was much emaciated and very weak, but the symptoms of pyloric obstruction were so severe that it was decided to operate. The tumor was adherent to the pancreas, and was separated with great difficulty. The operation lasted over two hours, and the patient never recovered from the shock, dying in ten hours.

In this case the duodenum was united to the stomach at the greater curvature, the resulting stomach being much better in shape than the first two.

It is readily seen that these two fatal cases were not as favorable for operation as the first one. Through the kindness of Dr. Mikulicz I was able to visit and examine this patient at her home about a week ago. I found her able to eat any kind of solid food, walking about the house, and entirely free from pain. At that time there were no symptoms of recurrence.

Since the above was written Dr. Wüller, assistant of Professor Billroth, has operated in another case, removing a malignant tumor of the pylorus. The stomach and duodenum were united as in Professor Billroth's third case. It is now six days since the operation; there have been no unfavorable symptoms, no vomiting or nausea, and the external wound has entirely healed. The intense pain present before the operation has entirely disappeared, and the patient takes all kinds of liquid food, oranges, etc., without discomfort, and sits up in bed.

SAMUEL J. MIXTER, M. D.

VIENNA, April 15, 1881.

THE Editor of the *Journal of Comparative Medicine* desires to secure as complete a list as possible of all persons practicing veterinary medicine in this country. No veterinary medical register now exists. It would tend to unite members of the veterinary profession, and benefit them in many ways, and would be a convenience to many others, if such a register were published.

All veterinarians are urgently requested to forward, by postal, their names, titles, and addresses. All such will receive a copy of the final list at cost rates. Address: Editor of *Journal of Comparative Medicine*, care W. L. Hyde & Co., 22 Union Square, New York City, N. Y.

REPORTED MORTALITY FOR THE WEEK ENDING MAY 7, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 3043; 1194 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 752, consumption 435, lung diseases 382, diphtheria and croup 211, scarlet fever 133, diarrhoeal diseases 85, cerebro-spinal meningitis 81, small-pox 62, typhoid fever 51, measles 40, malarial fevers 34, whooping-cough 18, puerperal fever 17, erysipelas 13, typhus fever seven. From *diarrhoeal diseases*, Chicago 36, New Orleans 16, New York 12, Philadelphia and Baltimore four, Brooklyn and District of Columbia three, Boston and Pittsburgh two, Providence, Lawrence, and New Bedford one. From *small-pox*, Philadelphia 35, New York and Chicago 12, Pittsburgh three. From *typhoid fever*, Philadelphia 11, New York eight, Cincinnati and Lowell four, Providence three, Chicago, Boston, Pittsburgh, and Buffalo two, Brooklyn, St. Louis, Baltimore, New Orleans, Charleston, Nashville, Fall River, Lawrence, Lynn, Holyoke, Newton, Milford, and Brookline one. From *measles*, New York 10, Baltimore seven, Cincinnati six, Chicago and Nashville three, St. Louis and Milwaukee two, New Orleans, Pittsburgh, Buffalo, Providence, Worcester, Cambridge, and Haverhill one. From *malarial fevers*, New York 14, Brooklyn seven, St. Louis six, New Orleans three, Cincinnati two, Baltimore and District of Columbia one. From *whooping-cough*, New York and Chicago five, Philadelphia, Brooklyn, and Pittsburgh two, St. Louis and Cincinnati one. From *puerperal fever*, Milwaukee three, Philadelphia, Brooklyn, Boston, Pittsburgh, and Lynn two, St. Louis, New Orleans, Lowell, and Holyoke one. From *erysipelas*, New York seven, Brooklyn three, Charleston two, Chicago one. From *typhus fever*, New York six, Buffalo one. The mortality from cerebro-spinal meningitis has increased from 60 for the week ending April 30th to 81.

Seven cases of small-pox were reported in Brooklyn, 32 in Chicago, one in Boston, three in Cincinnati, five in Pittsburgh, one in Springfield; diphtheria 51, scarlet fever 16, in Boston; scarlet fever 36, diphtheria 11, in Milwaukee.

In 41 cities and towns of Massachusetts, with a population of 1,088,239 (population of the State 1,783,086), the total death-rate for the week was 20.99, against 22.39 and 21.26 for the previous two weeks.

For the week ending April 16th, in 149 German cities and towns, with an estimated population of 7,783,192, the death-rate was 27.1. Deaths reported 4053; under five 1809; pulmonary consumption 621, acute diseases of the respiratory organs 450, diphtheria and croup 164, diarrhoeal diseases 104, scarlet fever 76, typhoid fever 64, whooping-cough 47, measles and röteln 24, small-pox (Königsberg five, Lübeck, Benthien, Munich, two, Berlin four, Leipzig, Aachen six) 20, typhus fever (Königsberg two, Thorn three, Tilsit two, Greifswald) eight. The death-rates ranged from 16.4 in Essen to 40.8 in Augsburg; Königsberg 32.8; Breslau 26.9; Munich 36.9; Dresden 31.9; Berlin 23.9; Leipzig 18.5; Hamburg 26.2; Hanover 18.7; Bremen 24.6; Cologne 28; Frankfurt 20.5; Strasburg 35.8.

For the week ending April 23d, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 22. Deaths reported 3211: acute diseases of the respiratory organs (London) 338, small-pox (London 84) 85, whooping-cough 84, measles 71, scarlet fever 63, fever 31, diarrhoea 26, diphtheria 22. The death-rates ranged from 17.1 in Hull to 29.9 in Newcastle-on-Tyne; Bristol 19.7; Birmingham 19.9; Leeds 20; Manchester 21.5; Sheffield 21.5; London 23.5; Liverpool 27.3. In Edinburgh 22.3; Glasgow 23; Dublin 32.6.

The meteorological record for the week in Boston was as follows:—

Date.		Barom-eter.		Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OBITUARY.

DR. GEORGE W. GARLAND.

DR. GEORGE WATERHOUSE GARLAND died at his residence in Lawrence, May 5th, after a comparatively short illness, at the age of sixty-eight. He was born in Barnstead, N. H., in 1813. His early education was received in the academies of Gilmanton and Hopkinton, N. H., and afterwards for three years he taught school to obtain the funds necessary for the pursuit of his chosen profession. His medical studies were commenced under Dr. Dixie Crosby, and further pursued in the medical school of Dartmouth College and at Harvard. While at the latter place he acted as surgical assistant in the Massachusetts General Hospital, and in 1837 he received his degree of M. D. from Bowdoin College. He returned to his native town, where he practiced his profession for eight years, when he removed to Meredith, now Laconia, N. H., and in 1851 he settled in Lawrence, with whose early history his name is closely identified. As a practitioner he was widely known and universally respected. He has been president of the Essex North District Medical Society, and a councillor of the state society, and in 1879 he delivered the annual oration before the Massachusetts Medical Society. He has contributed many articles on medical subjects to various journals, which have marked him as a man of unusual resources and fertility of invention. The paper on Obstetrics, read before the state society several years ago, and printed in its Transactions, contained several new and useful suggestions.

His only son, George M., is already well known as a practitioner in this city.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 7, 1881, TO MAY 13, 1881.

KING, WILLIAM S., colonel and surgeon. His extension of leave of absence on account of sickness, granted him November 9, 1881, from A. G. O., still further extended six months, on account of sickness. S. O. 105, A. G. O., May 7, 1881.

McPARRIN, T. A. His promotion to assistant medical purveyor, with the rank of lieutenant-colonel, — vice Cooper, deceased, — confirmed by the senate May 10, 1881.

BACHE, D., major and surgeon. Relieved from duty in Department of California, to proceed to Philadelphia, Pa., and report by letter, on arrival, to the surgeon-general. S. O. 104, C. S., A. G. O.

McFELLEN, ELY, major and surgeon. To report to the medical director of the department to duty until further orders. S. O. 56, Department of the Columbia, April 26, 1881.

HARRIS, A., major and surgeon. Relieved from duty in Department of the East, to take effect June 1, 1881; then to report in person to commanding general, Department of the Missouri, for assignment to duty. S. O. 104, A. G. O., May 6, 1881.

MIDDLETON, J. D. V., major and surgeon. Relieved from duty in Department of the East, to take effect June 1, 1881; then to report to commanding general, Department of the Missouri, for assignment to duty. S. O. 104, C. S., A. G. O.

BROWN, J. M. His promotion to surgeon, with the rank of major, — vice McParrin, promoted, — confirmed by the senate, May 10, 1881.

BROWN, J. M., captain and assistant surgeon. Relieved from duty at Fort Garland, Colo., and assigned to duty at Fort Lewis, Colo. S. O. 86, Department of the Missouri, May 3, 1881.

HUBBARD, VAN BUREN, captain and assistant surgeon. Relieved from duty in Department of California, to proceed to New York city, and on arrival report by letter to surgeon-general. S. O. 104, C. S., A. G. O.

GARDNER, W. H., captain and assistant surgeon. Relieved from duty in Department of the South, to proceed to Washington, D. C., and report in person to the surgeon-general. S. O. 104, C. S., A. G. O.

KOEPFER, E. A., captain and assistant surgeon. Relieved from duty in Department of the Platte, to proceed to Philadelphia, Pa., and, on arrival, to report by letter to the surgeon-general. S. O. 104, C. S., A. G. O.

KING, W. H., captain and assistant surgeon. Relieved from duty in Department of Dakota, and, on expiration of his present sick leave of absence, to report by letter to the surgeon-general. S. O. 104, C. S., A. G. O.

DEWITT, C., captain and assistant surgeon. Relieved from duty in Department of the Platte, to proceed to Philadelphia, Pa., and, on arrival report by letter to the surgeon-general. S. O. 104, C. S., A. G. O.

CONNECTICUT MEDICAL SOCIETY. — The annual meeting of the President and Fellows will be held at the City Hall, Common Council Room, Hartford, at three p. m., Wednesday, May 25, 1881. The following is the usual order of exercises, after the credentials of the Fellows have been decided: Address to Fellows, by the president. Announcement of committees. Recess for election of nominating committee. Report of committee on unfinished business. Reports of special committees: on medical experts, G. W. Russell, M. D.; on sale of poisons, R. Baker, M. D.; on vital statistics, M. White, M. D.; on lunacy commission, A. M. Shew, M. D. Introduction of new business: report of treasurer, Dr. Edgerton; report of committee on county resolves; report of nominating committee and election of officers; report of committee on business; report of standing committees; report of committee on honorary members; report of auditing committee. The Fellows are requested to register name and address upon entering the hall. The annual convention (mass meeting) will be held at City Hall, Thursday, May 26th, commencing at nine a. m. The following is the usual order of exercises: report of secretary, C. W. Chamberlain, M. D., Hartford; report of committee on matters of professional interest, W. A. M. Wainwright, M. D., Hartford, chairman; The Early Recognition of Epilepsy, E. C. Seguin, M. D., New York; reception of delegates from other societies; reports of delegates to other societies; introduction of business, cases of interest, and discussion. Essays: Sympathetic Ophthalmia, S. B. St. John, M. D., Hartford; Non-Pharmacological Therapeutics, Henry Fleischer, M. D., New Haven; The Influence of Sudden Alterations of Temperature and Humidity upon the Respiratory System, C. B. Newton, M. D., Stafford Springs; Medical Progress and Changes, William Woodruff, M. D., Thomaston; Treatment of the Third Stage of Abortion, J. H. Grannis, M. D., Saybrook; Treatment of Lacerations of the Cervix, M. D. Mann, M. D., Hartford; Transmission of Bovine Tuberculosis from Infected Milk, Noah Cressy, M. D., V. S., Hartford. Voluntary communications.

TWO CASES OF TEMPORARY APHASIA.¹

"BRIGHT'S DIATHESIS."

BY T. M. ROTCH, M. D.

Ferrier² defines aphasia as follows: "The subject of aphasia is deprived of the faculty of articulate speech, and also very generally of the faculty of expressing his thoughts in writing, while he continues intelligently to comprehend the meaning of words spoken to him, or it may be to appreciate the meaning of written language. An aphasic individual knows perfectly well, as exhibited by his gestures, if a thing is called by its right name or not, but he cannot utter the word himself or write it when it is suggested to him. In his attempts, only an automatic or interjectional expression, or some unintelligible jargon escapes his lips, or unmeaning scrawls are set down on paper as writing. This affection is usually, at first at least, associated with a greater or less degree of right hemiplegia, but the motor affection of the right side, chiefly of the right arm, is often slight and transient, or may be wanting from the first, the only indication of motor paralysis being a paretic or weak condition of the oral muscles of the right side. The inability to speak is not due to paralysis of the muscles of articulation, for these are set in motion and employed for purposes of mastication and deglutition by the aphasic individual. The cause of this affection was shown by Broca (and his observations have been confirmed by thousands of cases) to be associated with disease in the region of the posterior extremity of the third left frontal convolution, where it abuts on the fissure of Sylvius and overlaps the island of Reil." "One of the most common causes of the affection is softening of this region, consequent on sudden stoppage of the circulation by embolic plugging of the arterial channels which convey its blood supply, by which the functional activity of the part is temporarily or permanently suspended." "The rapid recovery which so frequently occurs in cases of aphasia, especially of the kind due to embolic plugging of the nutrient arteries of the left centres, is not so much to be regarded as an indication of the education of the right centres, but rather of the reëstablishment of the circulation and nutrition in parts only temporarily rendered functionless." Ferrier, in speaking of the unilateral development of a bilateral function, mentions the interesting observations of Lépine,³ Russell,⁴ and others who have recorded cases showing that aphasia with left-sided hemiplegia occurs in left-handed people, and states also that there are other cases which seem to show that recovery of speech may take place after a lesion which has caused complete and permanent destruction of the left speech centre, quoting in support of this view the case reported by Drs. Batty Tuke and Fraser⁵ as follows: "A female patient was rendered unconscious by the occurrence of cerebral hemorrhage. On her recovery she was found to be totally speechless, and she remained so for an indefinite period. In process of time, however, the faculty of speech was restored in great measure, though never quite perfectly. Towards the end of her life she had difficulty in

recalling the commonest terms, but she never hesitated to articulate the word when she heard it. Death occurred fifteen years after the seizure, and there was found a total destruction and loss of substance in the cortical region in the left hemisphere corresponding with the position of the centres of articulation. This seemed to be one of the clearest cases of re-acquisition of the faculty of speech by education of the articulating centres of the right side."

In Mr. A's case, where there were no antecedent symptoms of cerebral disease, the cause of the aphasia appeared to be either a minute hemorrhage or an embolus, the embolic origin of the attack seeming to be more probable from the existence of an aortic heart murmur in a patient who had had articular rheumatism, and from the absence of any other symptoms which would be of aid in the diagnosis of hemorrhage, such as vomiting, infrequent pulse, stertor, changes in the pupils, convulsions, etc., which, according to Professor Austin Flint,⁶ suffice for a highly probable differential diagnosis though they do not warrant a positive opinion.

Professor Flint mentions the case of a young man who, having ridden all day in an open wagon, the weather being cold, after eating a hearty supper, was suddenly unable to utter a word. He went to bed, and slept perfectly well, but on awakening was still unable to speak. In the course of the day he began to use some words, often the wrong words, and in a few days recovered his speech, although he has ever since had some difficulty in selecting right words. He had an aortic regurgitant and a mitral direct murmur, with considerable enlargement of the heart. A year after the attack nothing had occurred to denote cerebral disease, excepting that he was conscious of an uneasy sensation in the left side of the head, and the case was considered to be of embolic origin.

The salient points of interest which immediately attract our attention in the case of Mr. B. are the evidence of a slightly hypertrophied heart without valvular lesion, in combination with a condition of the urine which might well indicate an early stage of interstitial nephritis, and an arterial pulse both in the fundus of the eye and at the wrist, supposed to show increased arterial tension.

This combination of physical signs has long been recognized, and the literature of the subject during the last five or six years has been extensive, different authors in succession reviewing the vexed question of the etiology and pathology of the disease, and criticising the theories of their predecessors, but it is interesting to note that although the mechanical theory of Traube and Johnson held such a prominent position among the earlier writers, yet that the later investigations, both physiological and pathological, tend to support the original view of Bright, suggested half a century ago, that it is an altered quality of the blood which causes disease of the heart, vascular system, and kidneys with their respective train of symptoms; Bright, however, seems to have considered that this change in the blood originated in the kidneys, while Mahomed,⁷ Saunby,⁸ Broadbent,⁹ and others hold that the altered blood is the primary condition which produces congestion of the excretory organs, especially the kidneys, thus leading to renal disease, and that this same poi-

¹ Concluded from page 462.² Functions of the Brain, page 272.³ Thèse Mongié, Paris, 1866.⁴ Medical Times and Gazette, July 11, October 24, 1874.⁵ Journal of Mental Science, April, 1872.⁶ Practice of Medicine, p. 660.⁷ Guy's Hospital Report, 1879.⁸ Birmingham Medical Review, 1878.⁹ Lancet, December 25, 1875.

soned condition of the blood also produces impeded capillary circulation, and the resulting cardio-vascular changes. Mahomed draws especial attention also to the value of the high tension pulse as the earliest physical sign by which we can not only foresee but in certain cases entirely obviate, or at least delay, the approach of chronic Bright's disease. Sanby considers that this disturbance is primarily in the digestive organs, and results in the imperfect oxidation of nitrogenous material, a function which Murchison¹ has shown to be chiefly located in the liver. This imperfectly oxidized material circulating in the blood directly stimulates the kidneys, according to Heidenhain, maintaining in them a constant state of functional hyperemia, and by increasing the general capillary resistance raises the systemic blood pressure so as to keep up a permanent strain on the organs of circulation, which results in dyspepsia, constipation, lassitude, muscular pains, coldness of extremities, later cardiac dilatation and hypertrophy, gastric and bronchial catarrh, etc., and still later, rupture of a small vessel, producing various symptoms, such as paralysis, aphasia, etc., according to its locality.

The extended and careful experiments of Grawitz² and Israel on dogs, in which they were able to produce this combination of hypertrophied heart and interstitial nephritis by the introduction of small amounts of urea into the blood showed that in no case was the arterial tension increased, and they therefore concluded that the impeded kidney secretion caused the heart hypertrophy, and that this hypertrophy did not depend on an increased arterial tension, but was caused by the small amount of urea, which, being retained in the blood, excited the heart to greater activity, and thus to hypertrophy. Finally, they admit that with our present means for diagnosis the difficulty of determining the exact time when the disease of the kidney or heart begins is so great that it is impossible to say which begins first, but they consider as proved that under none of the conditions as yet brought forward by investigators is the blood tension increased, and they hold that the impaired renal secretion causing irritation and hypertrophy of the heart with increased velocity of the circulation produces dilatation of the vessels throughout the body.

These experiments of Grawitz and Israel should receive especial attention, for besides being evidently performed with the most faithful regard to detail, and in the most evident spirit of fairness, they had the advantage of coming after such prominent investigators as Senator,³ Ewald,⁴ Grützner, Buhl,⁵ and Ustimowitsch,⁶ all of whose experiments they have carefully repeated and analyzed.

In regard to the pathology of the disease represented by the "Bright's diathesis" the literature is as extended and the opinions as diverse as has been the case in the discussion concerning the primary cause of the disease. The principal theories, however, which at present divide the opinions of the especial investigators of this subject, are those brought forward by Dr. Johnson, and by Drs. Gull and Sutton, the former at first maintaining that the pathology was mainly a hypertrophy of the muscular coat of the renal arterioles,

causing a continued contraction of their lumen, and later imagining a tonic spasm of all the systemic arterioles; while the latter believed that the disease was primarily a degeneration of the vascular system at large, the affection of the kidney and heart being a secondary manifestation; and they also considered that what Johnson supposed to be a hypertrophy was in reality a peculiar hyaline fibroid substance deposited in the muscular coat of the arterioles, and they therefore designated the disease arterio-capillary-fibrosis; and one of the chief merits of this theory (as observed by Dr. Ball⁷ in his review of the subject) is that it directs attention to the systemic changes, which from a diagnostic point of view are frequently more important than the purely renal symptoms. Dr. Thoma,⁸ who has made a most extended study of the subject, has failed to discover the muscular hypertrophy upon which so much stress is laid by Dr. George Johnson and his followers, and his views coincide very closely with those advanced by Sir William Gull and Dr. Sutton, so far, at least, as the renal process is concerned, and where he has noticed any changes in the muscular arterial coat they were rather in the direction of atrophy from stretching and compression by the proliferated connective tissue. On the other hand Bamberger⁹ was of the opinion that the hyaline-fibroid degeneration of Gull and Sutton was a product of microscopical preparation, though this cannot be said to have been clearly proved, as shown by Dickinson's¹⁰ experiments.

Dr. Bryan C. Waller¹¹ has lately given us the results of his investigations of forty-five cases where interstitial changes had occurred in the kidney, which afford but little support to the theory of arterio-capillary-fibrosis, and are decidedly in favor of Dr. Johnson's theory of hypertrophy of the middle coat. The following is a summary of Dr. Waller's work which extended over a period of five years:—

(1.) Certain changes in the vascular system are found in connection with chronic interstitial Bright's disease.

(2.) These changes consist principally of thickening of the middle and inner coats.

(3.) In the case of the systemic arteries the outer coat does not undergo any change which can be connected with the state of the kidneys themselves; it is sometimes secondarily blended with the surrounding increased perivascular connective tissue.

(4.) The hypertrophy of the heart is compensatory and secondary to obstructive causes. It seems to bear a definite relation to the degree of obliterative thickening in the tunica intima of the systemic arterioles. There will, however, be no hypertrophy if the general nutritive conditions of the system are markedly bad.

(5.) The changes in the arterial coats are in all likelihood due to the same primary cause as the alterations in the kidney stroma, namely, the circulation of poisoned blood, though the affection of the vessels is generally subsequent in point of time, owing to the more differentiated and therefore more stable nature of the vascular tissues and the non-occurrence of cell emigration into the arterial tunics as into the kidney stroma.

(6.) Interstitial changes may occur in the kidney apart from any alterations in the arteries, if the renal disease prove fatal before the latter have time to develop.

This is seen in cases of glomerulo-nephritis, where death generally occurs rapidly, with symptoms of suppression of urine, uræmia, and acute dropsy.

(7.) The general sequence of the various items in the morbid process appears to be (a) blood poisoning; (b) renal changes; (c) vascular changes; (d) cardiac hypertrophy.

Dr. Broadbent's cases illustrating clinically the symptoms of the "Bright's diathesis" and showing the great benefit that can be derived from treatment, I have not time or space to describe, but they are well worth the careful perusal of the physician in every-day practice, and can be found on page 202 of the *Lancet* for December 25, 1875.

In addition to the usual purgative treatment adopted in cases where this condition of high tension is found, it may be well to experiment with the one per cent. solution of nitro-glycerine used in a series of cases by A. W. Mayo Robson¹ with apparently good effect. One of these cases, a woman fifty-two years of age, consulted Dr. Robson in June, 1880, for attacks of dizziness; two days before seeing him she had an unusually severe seizure which had left her right side weak and had rendered her speech indistinct. The right side of the face and the right arm were found to be slightly paralyzed, and the right leg numb and decidedly weak. Her pulse was hard and corded, and all her vessels indicated increase of tension. The urine was normal in quantity, but had a specific gravity of 1006 and showed a trace of albumen.

Milk diet, aperient medicine, and rest were ordered, and the paralysis gradually passed off, but the vascular tension remained. In August she began to take the nitro-glycerine solution in minim doses, thrice daily, as the attacks of dizziness were returning; the vascular tension was at once reduced and the pulse became softer and apparently fuller; the urine, which just before the nitro-glycerine treatment had a specific gravity of 1008, increased afterward to 1012, and became slightly more abundant. Her dizziness was relieved, and when an attack was threatened, a dose of the remedy always prevented it.

Dr. Robson suggests that it would be advisable to give a dose of this remedy when called to a case of apoplexy, to prevent further hæmorrhage by reducing the pressure in the vessels.

I have given this short and imperfect review of what will probably in the future be called the "Bright's diathesis," thinking that Mr. B.'s case might come under this class, and that the two aphasic attacks from which he has already suffered may be the forerunners of serious disease which may possibly be obviated by a change of life. The tracings, judged by the rule laid down by Mahomed in his exhaustive article on this subject, that "no part of the tracing should rise above a line drawn from the apex of the up stroke to the notch preceding the dicrotic wave," show such a rise to be present, and this, according to Dr. James Putnam, who has made extended observations on normal pulses, does not occur unless the tension is abnormally high.

The examination of the urine in Mr. B.'s case is instructive and recalls the statement of Bartels,² who says that though the amount of urine falls, the specific gravity does not rise to the normal, as was seen in the analyses made by Dr. Hills, also that the urea is diminished, but is often masked for years by the polyuria.

APHASIA COMPLICATED WITH INSANITY.

BY C. P. BANCROFT, M. D., BOSTON.

J. G., a farmer, aged sixty, entered the New Hampshire Asylum for the Insane August 21, 1876, with the following history: Had always been perfectly healthy. No hereditary insanity. On December 6, 1872, worked hard all day in a severe snow storm, thereby getting wet and chilled. On the evening of this day he had an attack of loss of vision, and his entire right side was numb, though not completely paralyzed. Head was cold and covered with clammy sweat. Did not lose consciousness. Recovered in about a week. No mental derangement. Soon after this began to have most violent and distressing palpitation of the heart, and sensations of fullness and pain about the epigastrium. Aside from these symptoms he was as well as usual. On May 30, 1876, he suddenly became restless in the night, and seemed to be in distress. When asked what was the trouble, he seemed cross and irritable, complaining that his wife was always fault finding. It was noticed that his articulation was indistinct, and that he spoke with difficulty. He replied to questions asked that it seemed as though a string was pulling at his left eye; the pupil of that eye was widely dilated. There was no other paralysis aside from the left iris and tongue. Recovered in five days, although he remained for some time after in a state of complete physical prostration. On the 7th of June, 1876, he drove a spirited horse six miles, returning about midday much exhausted. Soon after returning he was seized, while sitting in his chair, with loss of speech, marked mental confusion, and apparently a temporary loss of vision. There was no paralysis. His eyes were rolled up, he groped his way about the room evidently seeking a door. He soon recovered the power of vocalization, but not of speech. For four days he knew no one, not even his own family. His mind was filled with all sorts of insane fancies. He would milk the cows three or four times a day, and then chain them to the stalls. At nightfall would nail the windows and doors. When admitted to the asylum in August, 1876, he partly understood the meaning of gestures, but attached no meaning to speech. Heart was regular and intermittent, but no murmur could be detected. He coined words of his own, but did not understand a word that was said to him. By September he had made slight improvement, as the record indicates. "On the whole has gained in the faculty of expression and in the matter of understanding signs and words. His sentences are more perfect and connected, and though he comprehends little of what is said to him, he does not look so utterly unconscious when addressed. Looks at the speaker as though he would like to get at his meaning if he could. In response to the written question, "Do you know where you are?" he said, "Well, I'll do the best I can. Yes, I'll promise if you'll let me go down-stairs." A piece of paper was handed him with the words written thereon, "Write on this paper," and he read it thus: "On — this — promise." Seemed to think the doctor was demanding money either as payment for his board or compensation for his release. Said he would have "to go home and sell something to raise the money." Finally wrote on the paper these words, "Gone as soon Thursday," pretty evidently meaning go home as soon as Thursday. At first wrote "Thursday" without an

¹ British Medical Journal, November 20, 1880.

² Ziemssen's Cyclopædia, volume xv.

h, but seeing the want of that letter took the pencil and made the correction.

The following is a stenographic report of the patient's conversation, and is a fair sample of his present method of expression: "I want to go home; yes, let me go home, won't you? I hain't said a word. What do they propose to do? Let me know right away. But I don't understand—Yes—No—I don't—No—I can't—if I did I would. No, I can't. I don't understand, and that." (At this point a piece of paper with writing on it was handed him.) "No, I can't read it; why, really, I can't read it. Now, if I could I would, but I can't—well, I can't—no, I don't. If they won't I suppose these old men were here." Always talks with the air of a man studying to make himself understood, and seems to think he is successful.

September 20, 1876. Wrote a letter to his wife, which is not only unintelligible, but is very illegible. Scarcely any of the words are correct; most of them are coined; even his own name is incorrectly written.

October 23d. Was induced to play at dominoes, and after his mind was centred on the game he could understand what was said relative to it.

November 2d. Had the following conversation today in regard to his method of moving and taking up trees: "You to take and cut a piece out, and with old axes, and then dig down under it, and take it out. You must be careful of the boshies so as not to injure them. I take out old boshies that way. Yes, you take an Irishman, and let him cut the ros right off, and you can take the brush out easy. Take and cut the ros right off, and brash the team right back, and then you can draw it right out. I always clean my broshies right off in the spring. You can't prow with brash just where you want to; you are liable to clash over on the smaller and hurt, and then you want to put a chain or rope, I don't know which he means; browse each way so you can light it as you please. Some climb up, and cut off part of brush, so that it will proll where they want it. You want to be careful and not streak it and gar it so as to spoil it when it falls." While speaking this patient seems to have no idea that he is not speaking correctly or that he cannot be understood. The words "brosh," "boshie" are very commonly used by him. In fact, these were the words that he first coined at the very beginning of his sickness, and his relatives say that he was continually using them for some time before he was sent to the hospital.

March 15, 1877. For the last few months has been gradually improving, though he has by no means recovered a perfect use of his faculties. The use of wrong words is not so marked as it was. (From this time until his death his ability to talk correctly slowly increased, but he could not understand language addressed to him.) His heart has been examined, but no organic lesion detected.

May 18th. It is doubtful if he has the faculty of reading intelligently, although he spends much of his time in apparently reading the newspaper. This morning brought a letter from home to the physician, but did not seem to understand its purport. Seemed to think there was something about doves in a passage which contained not the remotest allusion to them. May 31st. It was thought best to make a trial of sending him home, and he was discharged, improved.

On June 18, 1877, he was readmitted. Had no sooner arrived at home than he began to develop all manner

of eccentricities. At once became arbitrary and very unreasonable in all his wishes and demands. He did not in the least recognize his inability to speak correctly or to understand others, and was greatly incensed because his wife did not understand and do as he wished. Would not tolerate any restraint, and insisted on driving alone and doing in all things as he chose. Finally he even used threats, and his family were obliged to return him to the hospital. During his short stay at home the strain of being thrown upon his own responsibility wore upon him physically, and his expression became somewhat haggard.

On July 9th he was reported as much more hearty and robust than at time of readmission. On first coming back he was much excited and insisted on returning home, but later became perfectly reconciled. Whenever his wife called, however, he became quite angry with her, evidently thinking that she was the author of his detention.

From this time until the fall of 1878 there was little or no change. He would often talk for two or three minutes correctly, but he seemed wholly unable to comprehend what was said to him. At about this time he began to present the first marked physical symptoms of valvular disease of the heart. Had slight oedema of feet and ankles, and dyspnoea on exertion. Heart again examined when the following very marked changes were noted:—

"Heart's action very irregular; and the organ itself considerably enlarged; apex beat detected an inch to the left of mammillary line. Over sternum at junction of fourth rib is heard a systolic murmur propagated upwards toward the right; also a mild diastolic murmur. Over apex is heard a soft presystolic murmur." From the moment this examination was made the case became pathologically clear. The diagnosis of embolism was made. The embolus probably affecting the circulation in the anterior lobes of the cerebrum. Hitherto, as no positive heart murmurs could be detected, the case was somewhat obscure.

Mr. G.'s subsequent history was the usual one of valvular cardiac disease. Oedema, dyspnoea, cyanosis, palpitation, and pain; temporary relief with digitalis only to be followed by the ten-fold greater agony when this drug had reached its stimulating limit. Death occurred suddenly, while patient was sitting in his chair, on May 1, 1879.

Autopsy. Heart weighed twenty-seven ounces; wall of left ventricle one inch in thickness. Aortic valves ossified, very rigid and incompetent, and presenting three large spots of ulcerative endocarditis. Mitral valve ossified, rigid, but presenting no ulceration. Lungs very oedematous. Brain weighed forty-one and one half ounces. Dura mater quite firmly adherent in places. Dr. W. F. Whitney made the following report on the brain: "The branch of the middle cerebral artery, right hemisphere, supplying the anterior portion of the middle lobe, is entirely obliterated, and that portion of the brain representing a piece three to four centimetres in diameter is completely destroyed, simply a thickened mass of fibrous tissue covered it, enclosed in which the artery was found. The island of Reil is only superficially affected.

The anterior convolutions are untouched. On the left side nearly the same lesion occurred only very much smaller, and the anterior convolution was unaffected.

The case presents the following peculiarities: (1.)

At the beginning of his attack, and for a long time afterward, the patient seemed unconscious of any infirmity of speech. He thought he spoke correctly, and, unlike aphasic patients generally, was not disturbed by the fact that he was using the wrong word. He was even angry with his relatives because they did not understand him, and do as he bade them. It was undoubtedly here that his insanity played a prominent part, and prevented him from appreciating his own mental and physical condition. He seemed to have positive ideas; and to his own consciousness they were sufficiently reasonable. He milked the cows several times a day, chained them to their stalls, and nailed the windows, with the air of a man who understood perfectly well what he was doing, and recognized the importance and necessity of so doing. In the same determined manner he spoke and ordered his family to do this and that, never in any way indicating that he did not understand what he was about. It was only after a long residence among strangers that he seemed to discover that he was not understood.

(2.) He gradually recovered the power of speech, and was able to express his own ideas quite easily. The strange words that he at first used gradually disappeared from his vocabulary and he once more used the right word in the right place. But notwithstanding this he was wholly unable to understand language addressed to him. Many times have I endeavored to converse with him, but he never seemed able to understand and would invariably reply on some wholly irrelevant subject. For the last few months of his sickness he seemed conscious of this inability to comprehend remarks addressed him, and his expression was that of a foreigner who does not understand your language. At the same time his hearing was perfect; he understood gestures very readily, and played a good game of dominoes or checkers. Not only this, he could read understandingly. In short, he could comprehend ideas communicated by gestures or by writing and printing; but spoken language was wholly incomprehensible to him. On one occasion he received a local newspaper from his native place. There was an account therein of a runaway, in which an old friend of his was thrown out of his carriage and injured. He seemed to understand the account and read it aloud correctly to the physician, making some comments on it.

(3.) The lesion was peculiar. Ordinarily the third anterior convolution on the left side is destroyed or encroached upon in aphasia; if not in the left it is generally in the right hemisphere. In the present case this convolution was sound on both sides. This probably affords an explanation of the patient's recovery of speech to a certain extent. If the anterior convolutions on both sides had been diseased his aphasia would have been permanent in all probability. The probable sequence of pathological events in the case seems to me to be somewhat as follows. An embolus from the heart was swept into the left middle cerebral artery. This caused the numbness of the right side and the loss of vision, but the speech centre was not affected at this time. At the second attack undoubtedly another embolus was swept into the middle cerebral artery on one or the other side, it seems to me impossible to say which, causing the mental confusion and prostration. In the third attack still another embolus was carried into the circulation and probably this time the right side was affected as well as the left. The centre of co-ordination of language was not actually affected struc-

urally; but the disturbance of the circulation in that centre was so great that its function was entirely destroyed at the time. At the same time the general disturbance to the cortical portion of the brain, involving of course the centres of ideation, was so great that mental confusion resulted. Gradually, through the restoration of the circulation by collateral channels in the anterior convolutions, the power of co-ordinating language slowly but imperfectly returned, although a healthy state was never again reached.

The question arises, How can the fact be accounted for that he could understand ideas communicated in writing or printing or when expressed in gestures, while the very same ideas, expressed in spoken words, no matter how slowly they were uttered, were totally incomprehensible to him? The most probable explanation would seem to be that the nerve fibres conducting ideas from the auditory apparatus to the higher cerebral centres were actually interfered with and destroyed by disease. Whereas the nerve fibres conducting ideas from the visual organs were unimpaired. His hearing was perfect; the slightest sounds were heard by him. A spoken word, however, seemed merely to fall upon his tympanum and go no further.

The mental alienation made the case more blind, for the patient did not generally seem to think that he was laboring under any cerebral trouble. He considered himself well and strong and in full possession of his faculties; he always attributed the fault to others, not to himself. Hence it was impossible to carry on any intelligent conversation with him about himself.

TWO CASES OF SUBSCAPULAR ABSCESS; ONE OF THEM ATTENDED BY PERFORATION OF THE LUNG.¹

BY F. H. HOOPER, M. D.

THE first case of subscapular abscess which I shall report is one which presents some points of unusual clinical interest, and came under my observation last summer while conducting the service of Dr. Rotch at the Boston Dispensary. For the second I am indebted to the courtesy of Dr. E. H. Bradford and Dr. F. C. Shattuck, and to the records of the Massachusetts General Hospital. A careful search in medical literature has failed to find a single case identical, in all particulars, with the first, and only one which bears any resemblance to the second.

CASE I. C. D., a little girl two years and eight months old, was brought to the Dispensary on Tuesday, the 17th of August last, with the following history: Born in this country of healthy Irish parents, she has always enjoyed good health, never having had even the ordinary complaints of infancy. One week ago she began to show less life and ardor in her play, but there was no one symptom in particular calculated to excite the anxiety of the mother, unless it was that she noticed the child seemed to favor—to "nurse," as she expressed it—her left arm, and to carry it away from her side. On Saturday, that is, three days before her visit to the Dispensary, a small swelling, about the size of a pigeon's egg, was seen in the left axillary region at the border of the scapula. This increased rapidly in volume, the child becoming very peevish and restless, but there were no complaints of

¹ Read before the Suffolk District Medical Society.

pain. In the night between Monday and Tuesday the swelling burst (according to the mother) "inside." The child immediately began to cough and retch, and brought up two cupfuls of purulent matter of such fetid quality as to produce vomiting in the mother, who, I may add parenthetically, was six months pregnant. It was noticed that simultaneously with the evacuation of pus from the mouth the swelling diminished in size. Has coughed much since, and from time to time expectorated a little pus. When seen the following morning at the Dispensary, the child was very pale and feeble, with a short cough, but no expectoration. On examining the back the left scapula was found projecting from the side, being pushed outwards and backwards by a soft fluctuating tumor extending beyond the axillary edge of the bone and below the inferior angle. The skin covering the tumor was healthy. The swelling was unaffected by the respirations, which were quick and short. No fetor of the breath. A small abscess of the sculp was found on the top of the head. On auscultating the upper left back loud gurgling and metallic râles were audible over the spine of the scapula at a point situated about the middle of the spinous process, and covering an area as large as a silver dollar. Owing to the feeble condition of the little patient a more thorough examination was not attempted at that time. In the afternoon, however, I visited her at her home, and found, in addition to the auscultatory signs already enumerated, numerous fine, moist râles occupying the lower lobe of the left lung. Percussion normal at the base, but as it caused so much disturbance to the child the whole chest was not percussed. Right lung healthy. The expectoration had been saved, as directed: small in quantity, thick, of a yellowish color, and odorless. A microscopic examination showed it to be pus unmixed with blood or any lung tissue. Child very feverish.

The next day, August 18th. Has slept well. Has short cough, but no expectoration. Abscess appears to be smaller. The *gorgonillement* over spine of scapula has disappeared. Bronchial respiration and bronchophony in the same spot strongly marked. The stethoscopic signs in other respects unchanged. Temperature 101° F.; pulse over 150.

August 19th. Seen at 8.30 a. m. Slept well yesterday, but was kept awake in the night by the distressing short cough. Sputa scanty, but purulent. Temperature 101° F.; pulse about 160.

Four p. m. Vomits the milk and brandy, and refuses nourishment. Sherry wine substituted for the brandy.

August 20th. When seen in the morning the child was very uneasy and restless, having been kept awake since one o'clock by the cough and difficulty of breathing. The tumor has increased in size. The râles in lower left chest less numerous and coarser. Temperature 103° F.; pulse very rapid.

Returned at noon and attempted to aspirate. Although the abscess was punctured at two different points, and the largest trocar which accompanies the Potain aspirator was used, the result was negative. The point of the canula could be felt moving freely underneath the skin. The aspirator was proved to be in perfect working order.

August 21st. Slept well yesterday after the puncture. Not much cough. Skin over abscess normal, and not hot, but the scapula stands out more prominently even than yesterday, and appears to be float-

ing, as it were, on a bag of pus. As soon as possible, I returned, accompanied by Dr. Elliot, who kindly lent me his aid, and a free incision was made immediately below and to the inside of the inferior angle of the scapula. The incision was followed by a sudden explosion of air from the wound, and the discharge of about an ounce of thick pus. There was not complete collapse of the tumor after the operation, but by slight pressure the scapula could be forced down to its normal position. Air escaped with much noise from the opening with each cough or cry of the infant. A drainage tube was inserted, and a tight bandage applied to the chest.

August 22d. Much dyspnoea and cough, with purulent expectoration, but the pus is less thick. Has taken milk freely, and slept well. On the whole, condition no worse. As there were no signs of any discharge on the bandage it was not removed. Temperature 103.6° F.; pulse over 150.

August 23d. No particular change. Temperature 103° F.; pulse over 150.

August 24th. Cough, paroxysmal and severe, but not so frequent. When the child coughs, a loud, hissing noise, produced by the air passing out of the wound, can be distinctly heard through the bandage. The abscess has discharged a good deal. Bandage removed. There is still some bulging of the scapula, and considerable oozing of thin, sweet pus from the opening. Upper part of left chest, front and back, tympanitic on percussion. Respiration over spine of scapula in the region where the coarse, bubbling râles were heard strongly amphoric. At the base percussion normal, and the fine râles have been replaced by a few coarse, dry râles and roughened respiration. Child very weak and emaciated. Bandage reapplied. Temperature 102° F.; pulse 144. Saw the case again in the afternoon in company with Dr. F. C. Shattuck. Condition unchanged.

August 25th. Drs. Cabot and Bradford visited the child with me in the morning, and verified the auscultatory phenomena above mentioned. Coughs less. No expectoration. Much discharge of thin, but not fetid, pus from the abscess, which was dressed, and bandage reapplied. In the afternoon there was a marked change for the worse. Cough very distressing and frequent, and much shortness of breath. Temperature 101° F.; pulse over 160.

August 26th. Seems a little more comfortable. No expectoration excepting mucus. The scapula now lies flat against the chest wall, and the stretched and loosened skin upon and around it has the appearance of a large empty sac, the flaccid walls of which move in and out with each inspiration and expiration. The flow of pus the same as on the previous days. Temperature 99° F.; pulse 128.

Dr. Shattuck again examined the case in the afternoon, and furnished me with much useful counsel in regard to it.

August 27th. In the morning temperature 98.5° F.; pulse 120. Notwithstanding this marked decline of the temperature and of the rapidity of the pulse, the extreme pallor of the child, the increasing feebleness and loss of flesh, threatened an unfavorable termination. In the evening temperature 103° F.; pulse 152.

August 28th. At both visits I found the little girl very restless and irritable, very weak from loss of sleep. Morning temperature 102.5° F.; pulse 146. Evening temperature 101° F.; pulse about 160.

August 29th. Condition about the same. In the morning temperature 103.5° F.; pulse over 150. In the evening a little worse. Temperature 104° F.; impossible to count the pulse on account of its rapidity and the fretfulness of the child.

August 30th. Increased dyspnoea, but coughs less frequently. Respiration at the base of lung slightly roughened, but no râles. The loud amphoric sound at the top remains the same. Discharge diminishing in quantity and much thinner. From the first, as already stated, the pus has not been fetid. Temperature 104° F.; pulse exceedingly rapid and small.

August 31st. Coughs very little. Respiration rapid, short and labored. Appearance pale and waxy. Sleeps a little from time to time, propped up in bed, for she will not lie down, as she has been able to do heretofore. Temperature 103° F.; pulse about 160.

September 1st. Child died.

Every effort was exerted to obtain a post mortem examination, but all my arguments were met by that superstitious ignorance which so besets the path of the dispensary physician, and an autopsy was obstinately refused. In the absence, therefore, of a scientific examination, the explanation of the clinical facts must be left to theory and conjecture. Impossible as it is to determine with absolute certainty the exact nature and point of departure of the disease, we can, I think, by elimination come pretty near a rational solution of the problem. There are a few important features in the case which I wish to emphasize, and these are, that there was no evidence of any previous disease or injury of any kind; prominent constitutional symptoms were absent; there was merely general malaise for a week before the sudden evacuation of pus from the mouth; then, it was on the outside of the chest that the swelling first showed itself, and for some days continued to expand, before any noteworthy symptom appeared. The physical exploration made it evident that there was a cavity at the top of the left lung, connecting by a fistulous tract with another cavity situated beneath the scapula, from which pus was discharged as well as from the mouth. The inquiry naturally is, In what organ or tissue are we to locate the source of the pus, and by what mechanism was this condition of things brought about? The history of the case makes it very improbable that the primary trouble was either in the lung or pleura. An inflammatory abscess of the lung, arising independently of tuberculous disease, pneumonia, or of any other ascertainable cause, may, as we know from the examples recorded by Graves, Stokes, Trousseau, and others, occur. But, pus once collected in the lung, it is extremely unlikely that it would work its way out through the resisting chest wall, instead of emptying itself into the pleural chamber or through the bronchial tubes, where the resistance would be reduced to a minimum. We had no signs of fluid or air in the pleural cavity. Moreover, the quantity of pus discharged was larger than we could expect from a pulmonary abscess. It must also be remembered that it was external to the thoracic wall that the swelling first made its appearance, and, growing larger and larger, its final collapse, or partial collapse, was coincident with the evacuation of the purulent matter from the mouth.

Could it have been a case of circumscribed empyema, in which the pus penetrated the costal pleura and worked its way down beneath the scapula? I think

not. The position and shape of the swelling and the absence of adema are against "empyema necessitatis," which is commonly seen in the anterior portion of the thorax. Besides, there is no reason, the pus once having broken through the intercostal muscles, why there should be rupture of the pleura pulmonalis, as the pressure at that point would be slight. It might occur, however, from necrosis of the membrane, but the absence of all fetor in this case excludes any such cause. In spite of the rapidity with which disease travels in infancy, I cannot believe that an empyema could form in so short a time, and without giving rise to any more constitutional disturbance than was observed in this little patient. The character of the pus also was not that of empyema. For these reasons, in addition to some of those mentioned for doubting the origin of the affection in the lung, I shall exclude the pleura also from having been the seat of the primary trouble.

We come now to the cellular tissue between the costal pleura and the chest wall, and consider the identity or non-identity of this case with a rare form of disease described by Wunderlich¹ in 1861, and named by him peripleuritis. According to Wunderlich, peripleuritis is an inflammation of the subserous connective tissue of the pleura costalis, originating independently of traumatism, or of previous inflammation of the pleura. Wunderlich reported two cases, which were followed in the same year by two more from Billroth.² Still later, in 1874, Bartel³ presented three cases in the *Deutsches Archiv*; then Riegel⁴ added another in 1876. I shall not review in detail these cases, but merely recall to your memories the chief features of peripleuritic abscess, in order to determine if this case can be placed in the same category. Of the eight cases reported seven were adults, and one was a child ten years old. The disease was ushered in by severe constitutional symptoms, and in the majority of the cases the health of the patient had been impaired by previous disease. But when we come to the physical signs, our difficulties are increased, for the chief points given for arriving at the diagnosis of peripleuritic abscess could not have been applied in my case on account of the anatomical situation of the tumor. Riegel, in a careful summing-up of the subject, gives the following signs as characteristic of the disease: a circumscribed, fluctuating swelling of an intercostal space, the space above narrowed in consequence of the rib being pushed up; percussion flat over the tumor, which is not altered by changing the position of the patient; good respiration beneath the area of dullness; no displacement, or very little, of neighboring organs; the swelling becoming flaccid on inspiration, followed by increased tension on expiration; finally, the character of the pus.

I cannot say that this condition of things did not exist in my little patient at the commencement of her disease, but certainly, when first examined at the Dispensary, the picture was quite different.

Wunderlich lays great weight upon the fact that in peripleuritic abscess the pus is localized, and has no tendency to burrow into the pleural cavity. In only one of the cases reported did such an accident occur. In the others it was prevented from so doing by the adhesion and thickening of the serous membrane; in the

¹ *Archiv der Heilkunde*, ii. Jahrgang, 1 Heft.

² *Archiv für klinische Chirurgie*, ii. Band, 1 and 2 Heft.

³ *Deutsches Archiv*, Band xiii.

⁴ *Deutsches Archiv*, Band xix.

one, however, although there was no adhesion of the pleural layers, the pus did not offer to work its way into the pleural sac. In the case under consideration the pus was not only *not* localized, but burst through the pleural membrane, and the pulmonary tissue also. Although the phenomena observed in my case are at variance with many of those which are symptomatic of a peripleuritic abscess, I do not think that the possibility of the trouble having had its origin in the subpleural cellular tissue can be positively excluded. A very short experience has been sufficient to prove to me how seldom nature pays any attention to the descriptions which the books give of her diseases, and although a peripleuritic abscess never yet has shown a tendency to rupture into the lung, I can easily imagine that if the disease occurs in early life, when all the influences which govern morbid processes are so altered, an abscess forming in this situation would be as likely to work its way in one direction as in another. But notwithstanding this possibility, the clinical picture of this case differs so entirely from that of the cases described by the German writers that I hesitate about placing it in the same frame. I hesitate also because I think we can find an explanation nearer at hand, which, although I anticipate some contradiction, appears to me much more plausible.

Stokes,¹ in a very interesting chapter on Perforating Abscess of the Lung, details a singular case of an "abscess of the abdominal parietes resting on the convex surface of the liver, opening externally and also perforating the diaphragm and forming a fistulous communication with the bronchial tubes." The same principles for forming a diagnosis would be applicable, I suppose, in whatever portion of the thorax the abscess happened to be. The grounds he lays down are "the occurrence of new and extraordinary symptoms, coincident with the subsidence of the hepatic distention." In our case we had a "new and extraordinary symptom" in the shape of a sudden and copious expulsion of pus from the mouth, "coincident with the subsidence of the" subscapular distention.

Now I know no reason why inflammation should not take place and pus collect beneath the shoulder blade as well as in other parts of the body. And I hold it is not improbable that the beginning of the complications in this case may have been an inflammation of some tissue, muscular or cellular, either in the substance of an intercostal muscle or external to it, which, leading to suppuration, and spreading to the pleural membrane glued the two surfaces together; so that when the pus was discharged from the abscess it was prevented from emptying itself into the pleural cavity by this pathological bridge, over which it passed to the lung, to be evacuated by the bronchial tubes. The severe unilateral bronchitis is of course easily explained, and death finally resulted owing to the exhaustion of the vital forces.

I offer the next case as evidence, as far as it goes, in favor of this view. Owing to a strange coincidence, which, in fact, is so constant that it may almost be considered some occult law, namely, that when an unusual case presents itself it is sure to be followed by a similar one, so, a few days after the death of this little girl, another infant was brought to the Dispensary, who presented, externally, appearances almost identical.

CASE II. September 10th. Bennett Burke, seven-

¹ Diseases of Chest.

teen months old. Always a healthy baby till last July, when he began to be troubled with boils on his head, which his mother attributed, of course, to his teeth. About the 1st of September she noticed a swelling under the child's scapula, which, as it continued to increase in size, determined her to seek advice. Dr. Bradford kindly called me into his room to see the child, and I found under the left scapula a fluctuating tumor, extending about an inch below the inferior angle and beyond the spinal edge for the same distance, and reaching as high up as the spinous process. The scapula was forced outwards and inwards towards the axilla, and projected from the chest wall in the same wing-like manner as was noticed in the preceding case. The skin covering the swelling healthy. Instead of returning the next day, as directed, the child was carried to the Massachusetts General Hospital, where he was promptly operated upon by Dr. Beach. A pint of pus was removed, and in a week he was permitted to leave the hospital. This little fellow has remained in good health up to four days ago, and at present moment he has a slight bronchitis.

The resemblance of these two cases, before the occurrence of the vomit of pus in the first case, is very marked. Both of the infants had had collections of pus in other parts of the body, and neither of them had any symptoms other than those which usually attend the formation of a furuncle. The debilitating, oppressively hot weather last summer was certainly conducive to and prepared good ground for furunculi to flourish, as was sufficiently shown by the large number of children who applied at the Dispensary to be relieved of these unpleasant visitors. I am inclined to place these two cases in the same class, but of course further observations are necessary before any definite conclusions can be arrived at. In looking up the subject but one case was brought to light, reported by Dr. Kwasnickiego,¹ of Warsaw, and of which the following is a *résumé*: A woman, thirty-six years of age, strong and vigorous, who had never had any serious disease, came to the hospital complaining of great pain in the left side, loss of appetite, sleeplessness, and general malaise. She stated that a week previously she had carried a heavy bundle all day, and in the night first felt the pain, which has steadily increased. Physical examination showed some swelling of the left shoulder and complete immobility of the arm on account of the pain. The scapula, displaced from its normal position, was pushed outwards and backwards, thereby dragging the shoulder and arm downwards. The anterior border of the scapula very prominent. Skin over this region stretched; otherwise normal. No fluctuation; but on pressing the scapula downwards, the sensation is like that of pressing on a spring mattress. A free and deep incision was made; half a glassful of pus evacuated, which was followed by immediate relief to the patient, and in two weeks her recovery was complete.

The dearth of information on the subject of subscapular abscess can perhaps be accounted for by supposing that the physicians into whose hands such cases have fallen have not deemed them of sufficient importance to be recorded. But, assuming that these cases belong to the same category, the first case shows us how the pus, from its proximity to a vital organ, may burrow

¹ Gazeta Lekarska, Warszawa, S. 28, Styczeń, 1867. Ropień Podłopatkowy (Abscessus Subscapularis), Dr. Kwasnickiego.

into it and destroy life, while the last two are of value as demonstrating the efficacy of proper treatment. And I feel, that had the subject of the first case received timely surgical interference her recovery also would have been a rapid and a happy one.

RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY E. G. CUTLER, M. D.

THE HISTOLOGICAL CHANGES IN CHRONIC PASSIVE CONGESTION OF THE SPLEEN.

NIKOLAIDES,¹ contributes an interesting paper on this subject. Such spleens feel dense and hard, and on their cut surface the pulp, at least in spleens the subject of old passive congestion, appears to be traversed by a very abundant thickened white network. When examined carefully, a thick white layer around the vessels may be detected with the unaided eye. It is a striking fact that such spleens do not present the dark-red color which we might expect, and such as is seen in kidneys and liver long exposed to passive congestion, but are often bright-red. Before proceeding to the changes observed, it might be well to briefly sketch the connection between the trabeculae and sheaths of the vessels, as well as that between the latter and the proper reticulum of the pulp, in order to understand the relation of the changes. It is well known that the capsule of the spleen, which surrounds the organ like a dense sack, is folded in at the hilus, at the point of entrance of the vessels and nerves, and thus becomes the sheath of the vessels. It accompanies the branching of the vascular system, being more strongly and voluminously developed around the arteries than around the veins, to their finest subdivisions. Besides the sheaths of the vessels and connected with them is another continuation of the fibrous splenic capsule directed inwards, namely, the trabecular system. The trabeculae penetrate the spleen in all directions with manifold divisions, and represent a very complex framework. They become firmly attached to the vessels, or run into them, especially the veins. Now with regard to the reticulum of the pulp, we know that it runs into the sheaths and adventitia of the vessels and forms around the cavernous veins a net of circular fine fibres, anastomosing at acute angles and forming a boundary to the blood current. Finally, the pulp-reticulum joins the trabeculae. From this the relation and interdependence of all these tissues is readily seen. Pathological histology shows that when a general irritation is present in the spleen, all these parts, on account of the continuity and similarity of the tissue, are productively aroused. This is the case in passive congestion of the spleen under consideration. Here, on account of the increased pressure within, all these parts are irritated and there results, as we see, that extensive thickening of the trabeculae and sheaths of the vessels.

To study the finer details of all these changes the spleen should be hardened first in Müller's fluid and then in alcohol. Sections examined under the microscope show the vessels, chiefly the arteries, to be enormously thickened, from increase of the adventitia and the sheaths which are closely connected with them. This thickening of the latter parts of the vessels forms a very broad zone of connective tissue, which runs over

into the adjacent reticulum of the pulp. Sometimes, particularly in very old spleens, tolerably broad connective-tissue bands are found running out from the sheaths of the vessels into the pulp, and between the fibres of the same fragments of cells. These bands of connective tissue are obviously nothing else than partial thickenings of the reticulum of the pulp continuous with the sheaths of the vessels, the pulp cells having subsequently disappeared, as is the case with the hepatic cells in the periphery of the acini in granular atrophy of the liver. The trabeculae are greatly thickened, especially where they join the wall of the vessels. Connective-tissue bands also run from the trabeculae towards the pulp.

These thickenings of the trabeculae, sheaths of the vessels, and adventitia are found more or less developed in all passive congested spleens, and the density of the latter depends on the degree of these thickenings. Naturally, we must not expect to find all these changes in those spleens in which the passive congestion has suddenly arisen, but only in those where the primary lesion causing the congestion has been slowly developed.

The above are the essential changes, but besides them there are others, namely, of the intima of the vessels, especially the arteries, and when the congestion has lasted a long time, of the veins also. The sort of change of the intima of the arteries is in so far different from that of the veins that in the veins of the parenchyma only a superficial fatty ulceration is to be observed, while the intima of the arteries shows an exquisite growth of all the connective-tissue layers, that is, a true endarteritis. Virchow has observed similar changes of the veins in other organs.² In valvular diseases of the heart he has seen in the intima of the pulmonary vein growths analogous to those in endarteritis, also in the portal vein in old passive congestion of the liver.

Nikolaides considers that there is also a thickening of the muscular coat of the arteries, above all of the circular fibres. The Malpighian follicles appear to take no part in the disease only in old congested spleens their border zone appears to be somewhat thickened. But primary changes of the follicles are not observed; we say primary, for the follicles may suffer secondarily in consequence of the thickening of the trabeculae and vessels.

To recapitulate:—

(1.) The essence of the passive congested spleen, or as it might, perhaps, be better termed, indurated spleen, is a thickening of the trabeculae and of the sheaths of the vessels and adventitia in connection with them.

(2.) The intima of the vessels, especially that of the arteries, suffers a very early induration, while that of the veins comes on after the congestion has lasted a long time, and has exerted a considerable internal pressure on the wall.

(3.) The reason of the slight hyperæmia of the spleen is to be found in the increase of the muscular coat of the vessels.

TUMOR OF THE TRICUSPID VALVE.

M. Garel³ relates a case of pulmonary disease in which jugular pulsation was accompanied by accentuation of the second sound. No other stethoscopic signs

² *Gesammelte Abhandlungen*, pp. 506, 507.

³ *Revue Mens. de Méd. et de Chir.*, November, 1880.

¹ Virchow's *Archiv*, Band 82, page 455.

were present. After death the tricuspid valve was found to be the seat of vegetations, and on that segment nearest the pulmonary artery there was a small tumor of cauliflower shape. Microscopic examination showed that it was an extravasation of blood into the tissue of the valve which had undergone fibrous transformation, and become in part calcified. Dr. Gibson¹ has also described a small tumor on the auricular surface of the inferior tricuspid valve, very near its attachment to the muscular wall of the heart of a sheep. The tumor was oval in outline, and measured four lines in length, and two and a half in breadth; it was of a deep purple color, with a smooth and glistening surface, the endocardium being everywhere perfectly healthy. After hardening, sections examined under the microscope showed the tumor to consist of blood clot undergoing organization near the proper tissue of the valve, the tumor being composed almost entirely of connective tissue, while the centre was composed of brown granular matter, the remains of broken-down blood corpuscles.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.²

T. M. ROTCH, M. D., SECRETARY.

Boston, May 7, 1881.

THE committee appointed by the Society for Medical Improvement to procure a portrait of Dr. J. B. S. Jackson, regret that so long a delay has necessarily occurred before making a report. We rejoice that we are able finally to present a well-painted and true portrait of our deceased associate. That now before you is a very exact copy of one painted by the late William M. Hunt, which has always been deemed remarkable, not only for giving the physical features of Dr. Jackson, but because it conveys to the beholder so much of the moral and intellectual qualities of our friend. It is a noble illustration of what high art, in the hands of a great artist, one capable of appreciating the finer traits of his sitter, can accomplish towards representing the best mental and moral qualities of the man before him.

This copy of Hunt's painting, which will hereafter belong to the Society, was made by Miss Rose Lamb, of this city. This lady was for many years an enthusiastic pupil of Mr. Hunt, and she seems to have drawn inspiration from her strong desire to exactly reproduce the portrait made by her master. The result is that we have now a most perfect likeness of our associate, who, "take him for all in all," was one of the most unique and excellent men our profession has produced during the past half century. We believe that the members of the Society will coincide with us as to the exactness of the likeness. It is hoped that it will hereafter silently speak to every one who looks at it, and stimulate all to be as true in their respective spheres of labor as he was in his department of medical science. That department which he so brought from nothing, as it were, in the university, up to that grand position in which he left it, namely, as a foundation for the modern science of the youths of the present day to build upon. How bright and genial, as well

as wise, are all the features which by this canvas will, we trust, be transmitted to physicians yet unborn! To gain this end, and that hereafter no such doubts may arise in the mind of any one as trouble those who study the portrait of what is called Ambrose Paré, now in our possession, we determined to fasten firmly upon the frame an inscription that will forever tell its tale. The inscription is in Latin. Some may doubt the expediency,—a so-called dead language, instead of English. We chose Latin for the following reasons: Because, besides giving a certain dignity to the subject, we can express more tersely than by English what we wish to say of Dr. Jackson, and of the reason for always keeping him and his example in remembrance. Moreover we deemed it not inappropriate to use a language honored and used by the learned of many past centuries, and which is daily, nay almost hourly, used to a limited extent at least by the medical profession of the present day throughout the civilized world. The inscription runs as follows:—

JOHANNIS B. S. JACKSON, M. D.
Anatomici Pathologici Prae-stantes: Anatomia Pathologica,
Profes. Harv.: Musci Pathologici Conditoris Societatis
pro Medicina Progressu Constituta, decoris et
praesidii, Haec tabulam Sodales ejus grate in
Memoriam dedicant
A. D. MDCCCLXXXI.

Can any one doubt that Dr. Jackson was a remarkable pathological anatomist? Was he not for more than forty years *facile princeps* in that department amongst us? Was not he known on both sides of the Atlantic for his great zeal in this line of work? How modestly yet unhesitatingly did he take that position of chief, and how willingly was it yielded to him by all of us! The microscope, chemistry, and all the more modern methods of studying pathological anatomy may carry forward his work far beyond the point to which he would have progressed by old routes, but they can never set aside the immense value of his labors.

He founded the museum now belonging to Harvard University, and which bears his name.

The words "decoris et praesidii," used by Horace in his Ode to Maecenas,³ and which we have chosen as suggestive of his relations to our Society seemed to us most appropriate. Will any deny that for years he was the honor and presiding genius of our Society. His fame has reflected honor upon us, and surely no one of us who remembers how often, evening after evening, he was the sole speaker and inspirer of our meetings can hesitate as to the propriety of the epithet "presidium," as applied in his relations to the Society, he was indeed for years our "presiding genius."

In conclusion we congratulate the Society that the painting has been paid for with the hearty coöperation of every one of our members. Not a few regretted that they were called upon for so small a sum as was required, when the cost of the painting was borne by so large a number.

We append three resolutions, which we hope the Society will adopt for the future care of the portrait.

HENRY I. BOWDITCH, }
CHARLES D. HOMANS, } Committee.
CHARLES P. PUTNAM, }

First. *Resolved*, That the Boston Society for Medical Improvement hereby requests the officers of the Boston Medical Library Association to take charge of

¹ Journal of Anatomy, vol. xiv.
² C. C. Arch. 1 from p. 120, 168.

³ Ode 1. Ad Maecenatem.

Dr. J. B. S. Jackson's portrait, on the condition that it shall be forever preserved in one of the public halls of the Association, or until otherwise ordered by this Society.

Second. *Resolved*, That a committee to make arrangements for the formal presentation of the portrait into the charge of Dr. O. W. Holmes, president of the Library Association, said presentation to be made at the next meeting of this Society.

Third. *Resolved*, That the members of the Library Association are hereby cordially invited to be present at that meeting, and that the secretary be and hereby is directed to send a printed notice to each member of the two associations giving information as to the object of the united gathering.

It was moved and carried that the same committee that had drawn up the resolutions should be the committee for presentation.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.¹

SECOND DAY. GENERAL SESSION.

The session opened with some lively and eloquent debate, in which Dr. N. S. Davis, of Chicago, and Dr. Dunster of the University of Michigan, figured prominently, the one in favor of and the other in opposition to an amendment to Article I, Paragraph 1st of the Code of Ethics. The amendment in question was as follows:—

Action on amendment to Code of Ethics, Article I, Paragraph 1st, add "and hence it is considered derogatory to the interests of the public and honor of the profession for any physician or teacher to aid in any way the medical teaching or graduation of persons knowing them to be supporters and intended practitioners of some irregular and exclusive system of medicine."

Dr. Dunster considered the amendment illogical in form, there being no connection between the paragraph to be amended and the amendment as offered; it was, he thought, moreover, narrow and mistaken in spirit. Medicine being a liberal profession we should do all in our power to extend the bounds of its usefulness, but this amendment would make the profession a most illiberal and proscriptive one.

The honor of a teacher does not depend upon those whom he teaches, but upon himself.

Another objection is that the amendment must always be inoperative even if adopted. There is no power to enforce this amendment either by legal, moral, or social measures. The enforcement of this statute would close every public clinic in America, because we are forbid to aid in any manner certain classes. There is also an objection because it is based upon the most fallacious assumptions. Now, if we teach the truth and the sciences as we believe, we know that no harm can result; if we adopt the amendment we concede that the dissemination of science leads to error.

Are you ready to say that no man shall teach the truth to all classes? Truth is the antidote of error, and sooner or later must conquer it. So far from denying truth to the unbeliever, we should do all in our power to extend its dominion.

On motion of Dr. Davis this amendment was made the special order after the addresses the next day.

Dr. John H. Packard, from the committee on journalizing transactions, presented a report, which recommended the establishment of a weekly journal as the organ of the Association.

The report closed with the following resolution:—

Resolved, That the president be authorized to appoint a committee of five to digest and report in detail as soon as practicable upon the time, place, and terms of the publication of such a journal, to elect an editor, fix his salary, and to arrange all other necessary details.

The report was discussed by Drs. Davis and Toner. Dr. Davis moved to strike out so much of the resolution as related to the election of an editor. Adopted.

Dr. J. M. Toner read the report of the committee on necrology.

SECTIONS.

I. STATE MEDICINE.—Dr. J. S. Billings, chairman *pro tem.*; Dr. R. G. Jennings, secretary.

Dr. J. L. Cabell, of Virginia, read a paper on The National Board of Health and the International Sanitary Conference of 1881. Dr. Cabell alluded to the illiberal action of the National Congress in reference to the National Board of Health, and spoke of the success that had attended the efforts of the New York physicians for the establishment of a State Board of Health. He also gave a history of the establishment of the National Board, and the reasons why it had not secured sanitary regulations in States which had not established State boards, and stated the reasons which impelled the calling of an international sanitary conference. Dr. Cabell proceeded to give an interesting account of the proceedings of that conference and the good work accomplished by it. After dwelling for some time upon the work prepared at the conference, Dr. Cabell concluded as follows:—

"There is, therefore, good reason for hoping that an international agreement may be arrived at between the states most frequently threatened with epidemic invasions. And, aside from this, the degree of attention which, as a result of the deliberations of the conference, has been given to the subject of maritime sanitary police, cannot be without fruit in securing greater cleanliness, better ventilation of ships sailing on the high seas, and, in general, an improved sanitary condition of these important instruments of commerce, which become so often the carriers of the most deadly contagion, from the failure to use such precautions as sanitary license suggests, and as it is hoped will now be enforced among the maritime powers of the world."

Dr. C. F. Folsom, of Boston, read a paper on the Relation of the State to the Insane, which will be published in full in these columns.

II. SURGERY AND ANATOMY.—Dr. Charles F. Stillman, of New York city, read a paper upon A New System of Surgical Mechanics, illustrated by numerous drawings and instruments.

The system demonstrated by Dr. Stillman is based upon the principle of *local extension* as opposed to *general extension* developed by all other systems, which local extension is produced by the use of the sector splint in the various forms shown by him as adapted to the several joints. Having given a cursory mention of Buck's extension, various modifications of the long splints, Hutchinson's method, and Thomas's plan,

¹ Continued from page 474. Our Reporter wishes to acknowledge his indebtedness to the Virginia Medical Monthly.

of Liverpool, he summed up the advantage of his system as follows:—

- (1.) Extension at any angle with motion.
- (2.) Extension at any angle with luxation.
- (3.) Fixation.
- (4.) Motion complete or limited, constant or occasional.

(5.) Exposure of surface about the joint, admitting compression, elastic or otherwise, hot and cold applications, blisters, dressings, and easy inspection.

This was followed by an exhibition of splints for the spine, hip-joint, knee-joint, ankle-joint, and elbow. Also an instrument for reducing cases of talipes in various forms and of long standing, by which instrument the surfaces of the tarsal bones are separated before the foot is made to assume a normal position.

Dr. Kinlough, of South Carolina, thought too much advantage was claimed for such contrivances, and was sorry he could not share the enthusiasm of Dr. Stillman, but had failed to secure as good results.

Dr. Quimby, of Jersey City, N. J., indorsed fully Dr. Kinlough's remarks. He thought mechanical instruments were sometimes useful, but were also capable of great abuse, and thought that they did not control muscular contraction.

Dr. Alfred C. Post, of New York, read a paper on Plastic Operations on the Face. He reported two cases upon which he had operated; in the first case after removal of an epithelioma involving the left side of the face, in the second case the plastic operation sought to repair the absence of the upper lip.

Dr. D. H. Goodwillie, of New York city, read a paper on Treatment of Arthritis of the Temporo-Maxillary Articulation, and reported cases treated.

Dr. B. A. Watson, of Jersey City, N. J., read a paper, the title of which was An Experimental and Clinical Inquiry into the Etiology and Distinctive Peculiarities of Traumatic Fever.

IV. PRACTICE OF MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.—Dr. Pepper, chairman of the section, delivered a very acceptable address. Instead of attempting a general and unnecessarily hasty review of the advances or discoveries in his department during the past year, he judiciously confined himself to a few practical remarks on some of the medical topics which have of late attracted most attention. In regard to one of the most prominent of these topics, the specific fevers or zymotic diseases, Dr. Pepper, though acknowledging the fascinating interest of the theories propounded to explain their genesis, and of the ingenious and plausible methods of treatment based thereon, thought it well that the wide difference between the amount of fluent writing and talking about septic processes and zymoses, and the amount of positive and demonstrable knowledge as yet acquired about them should be kept in mind. The subject of blood-poisoning having rapidly become one of the fashionable topics of the day, the terms and hypotheses devised by investigators have become the common property not only of general practitioners, but of the public at large, of the sanitary engineer, and of the sanitary plumber. The too-ready adoption of the popular theory of blood-poisoning will lead to mere scientific expectancy, to the use of routine methods, to the disregard of that watchful and minute care in adapting remedies to the morbid conditions, and the functional derangement present that constitutes the sole basis of rational and successful practice. Such scientific ex-

pectancy or routine practice will certainly impede and postpone the otherwise very possible discovery of new and valuable specific remedies. But, in the opinion of the speaker, the most serious practical injury which follows the excessive prevalence of the doctrine of specific self-limited diseases, is the tendency to underestimate the importance of local lesions, and of peculiarities of individual constitutions, as explaining the symptoms and determining the cause of diseases. Even in typically specific diseases, as, for instance, in typhoid fever, observation convinces one daily more and more strongly that it is impossible to get the best results from treatment without paying the most careful attention to these questions. Again, the fact that circumscribed catarrhal irritation of a mucous membrane, unattended with any considerable amount of catarrhal discharge, is able to excite marked febrile action, is a matter of the greatest practical importance.

Dr. Pepper enlarged considerably upon this topic, and in conclusion said:—

I have been led much further in these remarks than I proposed to go, but I have been drawn on by the sense of the great practical importance of a clearer recognition of the large part played by local catarrhal inflammation in the causation of symptoms now too readily attributed to some hypothetical specific or zymotic process. I do not feel at all satisfied with the theories of treatment largely based upon these hypotheses that are found in the works on medical practice, for the most part translated from foreign languages, which burden our shelves. I am sure they do not accord with the sound practical experience of American physicians, and do not meet the conditions of disease with which we are familiar. I am hopeful that ere long a truly national American system of medical thought and teaching will be developed which shall be animated by a more practical spirit, and shall embody the results of the broadest and most thorough clinical work.

When published in full Dr. Pepper's address will well repay careful perusal, and we regret that our crowded columns should make so brief an abstract unavoidable.

Dr. King, of Washington, read a paper by Dr. Prentiss, of New York, entitled Is Croupous Pneumonia a Zymotic Disease? The writer maintained that croupous pneumonia was a constitutional disease; that the lung affection was purely a local manifestation, and that, therefore, pneumonia must be classed among the zymotic and preventable diseases. The differential diagnosis between croupous and catarrhal pneumonia was dwelt upon, the writer claiming that the two diseases had only one point in common, namely: That in both there was an inflammation of the lung, and that, in fact, catarrhal pneumonia was merely a local disease, while croupous pneumonia was a constitutional disease, with a local (lung) manifestation. The specific cause of croupous pneumonia yet remained undiscovered; the disease must run its course, and treatment must therefore be symptomatic. He urged the importance of giving croupous pneumonia its proper classification in mortuary statistics.

Dr. W. C. Dalney read a paper on The Nature and Treatment of Pneumonia, and arrived at the following conclusions:—

Two views are held as to the nature of pneumonia—one that it is a specific fever; the other that it is a local inflammation of which the fever is symptomatic.

Arguments in favor of the first view : —

(1.) The disease ordinarily commences with a chill.
(2.) The constitutional disturbance is often out of proportion to the local disease.

(3.) The disease usually runs a definite course, and is self-limited.

(4.) The disease occasionally occurs as an epidemic.

Arguments in favor of the second view : —

Traumatic pneumonia is precisely similar to the idiopathic form.

The indications of treatment in the first stage are :
(1.) To lessen the amount of blood in the lungs and to check, as far as possible, the extension of the inflammation. (2.) To reduce the temperature ; and (3.) To relieve pain.

To fulfill the first indication, blood-letting, diaphoretics, saline purgatives, and cardiac sedatives are to be employed.

To fulfill the second indication, quinine is the most important agent.

To relieve pain, sinapisms, wet and dry cups, and opiates may be resorted to.

In the second stage, the indications are : (1.) To lessen the consistency of the fibrinous exudation ; and (2.) To prevent over-distention of the heart.

To fulfill the first indication, alkalies, especially carbonate of ammonia, are to be employed.

To fulfill the second, alcoholic stimulants are especially useful. Digitalis may also be used with advantage. If so much respirative surface is involved as to interfere seriously with respiration, oxygen gas should be used.

In the third stage, tonics, a nutritious diet, etc., are advisable.

The chairman said that the reading of these two valuable papers having been finished, he would now call for the discussion on this, one of the most important subjects now before the medical profession.

Dr. Lynch, of Baltimore, opened the discussion, and said that the various arguments which go to prove that croupous pneumonia was a zymotic disease had failed to convince him that such was the fact. If it was a zymotic disease, then the treatment was a matter of little or no importance, and should be merely symptomatic ; while if it was a local disease, the treatment was of great importance. He believed that it was often aborted by the use of the proper remedies, and had often seen the so-called defervescence produced in a few hours by the use of *veratrum viride*.

Dr. Whittaker classed himself with those who believed croupous pneumonia to be an acute infectious disease (not, of course, contagious). One point in the differentiation of this disease had not been brought out, namely : Catarrhal pneumonia attacked old people principally, while croupous pneumonia was confined to young ones. This, he thought, was a point of importance in the diagnosis of cases.

Dr. Burlington, of Vermont, did not think we could begin to treat the disease intelligently until we had determined its cause.

Dr. Lester, of Missouri, had failed yet to hear the argument which convinced his mind that pneumonia was a zymotic disease. He thought, also, that the discussion yesterday proved conclusively that blood-letting was applicable to a very limited number of cases.

Dr. N. S. Davis, of Chicago, had never been able to decide that pneumonia was zymotic, but believed it to be local. He rose to protest against the course of rea-

soning pursued by some members. Even assuming that pneumonia was a zymotic disease and run a definite course, this was no reason why it might not be cut short, and the physician had no right to fold his hands and do nothing because of such reasoning.

Dr. Oeterlony said that it seemed to be settled by discussion that if pneumonia was a zymotic disease it could not be cut short, but if local, it could. Pneumonia, he thought, was a self-limited disease. In regard to the zymotic character of the disease, he must confess, his mind had not been convinced ; thought it local ; wished to call attention to the danger of death from heart-clot. He thought carbonate of ammonia useful in other stages besides the third.

Dr. Ball, of Ohio, thought the idea of pneumonia being a self-limiting disease, and founding treatment upon that idea, to be exceedingly erroneous, and calculated to do great harm. He thought the disease could be cut short, and called attention to the method of treatment by repeated emetics early in the case, and claimed that it was valuable in aborting the disease.

Dr. McCaul, of Michigan, thought that in his State venesection was not admissible, and that cardiac sedatives must be used with extreme caution. Did not think the disease was purely zymotic, but that there was a zymotic condition of blood which tended to produce it.

Dr. Whittaker, of Cincinnati, asked if pneumonia were a local disease, what caused it ; certainly exposure did not. We had, he thought, no right to call it a local disease until we knew its aetiology.

On motion of Dr. Davis, of Chicago, the discussion upon this subject was closed, and the papers referred to the appropriate committee.

The secretary read by title a paper by Dr. Robertson, of New York, who was absent, entitled, *Nature and Treatment of Pulmonary Phthisis*.

The time until adjournment was then occupied in the reading, by Dr. Bulkley, of New York, of an interesting paper on the Diet and Hygiene of Eczema.

V. OPHTHALMOLOGY, OTOTOLOGY, AND LARYNGOLOGY. — Dr. Carl Seiler, of Philadelphia, read the first paper, on Syphilitic Laryngitis. He stated that the affection could be diagnosed from non-specific inflammation by the peculiar discoloration of the mucous membrane and the symmetrical disposition of the inflammatory patches. There are frequent ulcerations of the larynx, which may be divided into shallow ulcers, in nothing differing from those seen in catarrhal laryngitis, and deep ulcerations, which were, in the author's opinion, due to the breaking down of the smaller or larger gummata in the mucous membrane. He also stated that a diagnostic sign of syphilitic laryngitis was seen in the red lines and observed upon the *velum palati*. He recommended as treatment, beside the systemic, with iodide of potassium and mercury, and supportive with tonics, etc., local touching of the shallow ulcers with solid nitrate of silver fused upon an aluminum probe, and the deep ulceration with acid nitrate of mercury (1 to 4), or the galvanic cautery.

The subject being open for discussion, Dr. Reynolds said that he thought constitutional treatment would do more good than any local measures. He was surprised at the statement of Dr. Seiler, that the diagnosis of the simple form of syphilitic laryngitis was difficult. He did not believe that catarrhal inflammation could produce ulceration.

He thought that local applications could give no

good results unless restricted to such remedies as would give relief from pain. While not doubting the correctness of Dr. Seiler's observations, he differed with him in his diagnosis.

Dr. Stephens, of Hartford, thought the treatment much more satisfactory when both local and constitutional remedies were employed.

Dr. Walsh said that he thought too much prominence was given to the iodide of potassium. He held the opinion that the shallow ulcer corresponded in its time of appearance with the mucous patch of syphilis, and the deeper ulceration with the tertiary stage. He always found enlargement of the cervical glands in specific laryngitis. He employed mercury internally, especially in the shallow ulceration, and iodide of potassium in the deeper forms. He thought Dr. Reynolds wrong in neglecting local medication, the combination of the local and constitutional treatment giving better results. Of the modes of administering mercury, he preferred inunction. Treatment should be supporting.

Dr. Seiler closed the discussion, saying he thought catarrhal inflammation could produce ulceration. The infiltration of the submucous tissue could break down and produce ulceration. In his paper he had taken it for granted that any physician would employ constitutional treatment in this disease. He claimed that local treatment lessened the amount of cicatricial contraction in the process of cure. The application of caustic served to coat over the ulcer and protect it. He claimed that there was involvement of the cervical glands often in non-specific laryngitis, while it was not a constant symptom in the specific form. He based his diagnosis mainly upon the carmine color of the mucous membrane and the symmetrical arrangement of the ulcers. If there was an ulcer upon one side of the larynx there would be found a corresponding ulcer or focus of inflammation on the other side. He attached much importance to the red lines upon the velum palati, which were sometimes brought out by the irritation of an examination.

Dr. Chisholm read a paper on a form of tinnitus induced by a rhythmical contraction of the tensor tympani muscle, which was first brought to his notice by a muscular twitching in his own left ear. It occurred during the heat of summer, and invariably commenced after dinner. The twitching at first was not of more than half an hour's duration. It did not affect the hearing. The next day after dinner the buzzing sound was resumed. This followed for four days in succession. The duration of the buzzing now was gradually increased until the last recurrence. The noise continued until lost at bed-time in sleep. Inhalation of air-chloroform vapor, electricity, both faradic and continuous, did not in any way control the buzzing sound. The fluttering was felt at the drum head, and analyzed as a rhythmical contraction of the tensor tympani muscle. The contraction and relaxation varied at times from one hundred and thirty to one hundred and sixty to the minute. The cause was ultimately found to be a glass of wine, taken at dinner, in connection with the very hot weather. Omission of the wine stopped the noise, and its resumption at dinner renewed it. Other cases of a similar nature have come under the observation of Dr. Chisholm.

VI. OBSTETRICS AND DISEASES OF WOMEN.—The proceedings opened with a discussion as to whether there was or was not an investing capsule proper of

uterine fibroids, in which various opinions were expressed.

Dr. H. P. C. Wilson, of Baltimore, next exhibited some uterine dilators of his own construction. The relative merits of such contrivances and of tents were a good deal debated by different speakers.

Dr. H. O. Marcy, of Boston, exhibited his double drainage and injection tubes.

Dr. Jas. R. Chadwick, of Boston, chairman of this section, delivered an address devoted to a statistical consideration of the whole volume of literature upon the branch of medicine to which this section is assigned during the past five years. This address is too long and valuable to be done justice to in our limited space. In conclusion, he said:—

"To America I have no hesitation in according pre-eminence in this special field. Our countrymen meet the emergencies incident to child-bearing with a quickness of perception and readiness of action rarely seen in other countries. Their ingenuity has led them to devise new operations in gynecology, and to carry their art with brilliant results, so that to-day the practice of that branch has reached a stage here far in advance of other nations. Of course our natural aptitudes lead many of us to overestimate the beneficial results of surgery. Close observation and study in most of the countries of Europe has confirmed me in the opinion that in obstetrics and gynecology America leads the world. The two most prominent exponents of our branch in America, *The American Journal of Obstetrics* and the Transactions of the American Gynecological Society, present a more happy blending of scientific facts and practical suggestions than is found in any other special gynecological or obstetrical journals in the world."

We hope to publish the address in full at a later date.

PROCEEDINGS OF THE CONNECTICUT RIVER VALLEY MEDICAL ASSOCIATION.

THE annual meeting of the Connecticut River Valley Medical Association was held at Bellows Falls, Vermont, May 4, 1881. The president, Dr. Richardson, in the chair. Thirty members present.

CASE OF OVARIOTOMY.

Dr. D. Campbell reported the case. Mrs. F. R., aged fifty-six, mother of six children, first noticed a "bunch" in the right side some twelve years ago. She was tapped the first time, June 10, 1872, and eight times subsequently. The fluid discharged had the ordinary ovarian appearance up to November 14, 1880. At this time the cyst contained sixteen pounds of a fluid of a decidedly purulent character.

For the last three months the patient's general health had rapidly declined. She was greatly emaciated, with rapid pulse, high temperature and night sweats. It was evident that the case must terminate fatally in the near future without the radical operation, and it was decided to attempt the removal of the cyst. The operation was done December 16, 1880. Drs. George L. Foster, D. P. Webster, of Putney, and E. R. Campbell, of Bellows Falls, assisted, J. W. Keyes, D. M. D., having charge of etherization. The cyst was extensively and firmly adherent to the abdominal walls and to the omentum. The vascular supply to the cyst

was more extensive through the omental vessels than from the pedicle. The cyst contained fourteen pounds (by estimation) of fetid pus, with a quantity of gas. The pedicle was long, and tied in halves with carbolized silk and dropped back into the pelvis. The omentum required three ligatures. A cyst somewhat larger than a kidney was found in the left ovary, tied and removed. It contained a substance exactly resembling soft faecal matter, but without odor.

The usual antiseptic precautions were observed, as far as circumstances would permit. The abdominal wound healed kindly, and the sutures were removed on the twelfth day. Up to this time the temperature was below 100° F. On the sixteenth day the temperature rose to 102° F., the highest point at any time after the operation. No chill and no complaint of abdominal pain or tenderness at any time since the operation. On the eighteenth day, matter began to discharge slightly from the pubic extremity of the wound, and on the nineteenth day, while on the stool, an abscess burst, discharging a large amount (estimated eight ounces) of extremely fetid pus.

January 4, 1881, the twentieth day after the operation, the double ligature, with some two inches of the pedicle, was discharged.

From this date the case progressed favorably, the temperature and pulse becoming normal on the twenty-second day.

It is somewhat remarkable that peritoneal inflammation terminating in suppuration should produce so slight constitutional disturbance, and should be present without the slightest abdominal pain or tenderness.

It is also remarkable that the sloughed pedicle, with the double ligature attached, should find its way out of the abdominal cavity on the twentieth day after the operation.

The after-treatment was conducted by Dr. Foster, and much credit was given him by Dr. Campbell for the favorable result of the case. The two evacuated cysts were exhibited to the Association.

POPLITEAL ANEURISM FOLLOWING AMPUTATION.

Case reported and patient exhibited by Dr. C. A. Allen, Aeworth, N. H.

A. H., male, aged twenty-two, single, received an injury to his right knee, when three years old, which resulted in ankylosis of the joint. He does not remember walking without crutches, and, from want of use, all the muscles of the limb were atrophied. In July, 1880, he fell from a horse-rake, severely injuring the ankylosed knee. The resulting inflammation was severe enough to cause necrosis of the joint, for which the thigh was amputated by Dr. D. Campbell, September 21, 1880. At the point of amputation, the lower third of thigh, the main artery was about half the usual size, with very thin walls. The operation was performed antiseptically, vessels tied with carbolized catgut, and the usual dressings applied. On the sixth day dressing renewed. Upper half of wound healed by first intention, and no pus. Dressed again the ninth and twelfth days, and seemed doing well. On the thirteenth day after the operation active hæmorrhage took place, which was quickly controlled by the nurse with pressure over the femoral artery. Dr. Allen used styptic dressing, compresses, and pressure sufficient to check the force of the blood current. The sixteenth day there was another hæmorrhage, more copious than the first, but controlled in the same

way. On the nineteenth day there was a third hæmorrhage. In consultation with Dr. E. R. Campbell the propriety of ligating the femoral was discussed, but it was finally decided to temporize, as the last hæmorrhage was slight and easily controlled.

October 30th, forty days after amputation, stump was healed, and case dismissed.

December 4th. Was again called to see patient. A small abscess had formed and opened in the line of the cicatrix, and was discharging a sanious fluid containing but little pus. Abscess healed slowly. On the morning of the twenty-fifth of same month was hastily summoned, and found copious hæmorrhage had taken place. In consultation with Drs. D. and E. R. Campbell it was decided to ligate the femoral at once. Dr. D. Campbell performed the operation. After ligating, the end of the stump was opened, and it was found that the coats of the popliteal artery had not been firm enough to retain their position while a plug was forming, but had gradually distended, forming an aneurism the size of a small hen's-egg, which had burst, causing the hæmorrhage. The upper wound healed kindly, although the patient had an attack of scarlatina, coming on the day following the last operation, which ran its regular course.

The stump has been very tardy about healing, owing, probably, to deficient blood supply and want of innervation.

ANCHYLOSIS OF BONES OF HAND.

Dr. Albee presented a patient whose hand had been caught in machinery a few months before, and all the soft parts of the palmar aspect were torn away. The hand healed by the aid of skin-grafting, but most of the carpal and metacarpal bones were ankylosed.

Dr. Porter read an interesting paper entitled *Life*.

Dr. E. R. Campbell presented a paper on

THE INFLUENCE OF REPARATIVE SURGERY ON AMPUTATIONS.

He claimed that the more modern artificial limbs had greatly modified the form of amputation, especially above the ankle-joint. Syme's amputation is now considered preferable by all intelligent surgeons to any amputation at a higher point. The supra-malleolar amputation should always be preferred to one at a higher point, where, from the nature of the injury, Syme's is impossible. At the present time many excellent surgeons prefer a Syme to a Chopart operation, as an artificial limb can be better adapted.

The president, on retiring, conformed to the by-laws by reading a paper on *Death*.

Dr. Loveland reported a case of attempted cure of morphia habit, resulting fatally. The case was reported in this journal March 31, 1881.

Recent Literature.

What every Mother should Know. By EDWARD ELLIS, M. D. Philadelphia: Presley Blakiston. 1881.

A very good little book, written with discretion and good sense.

— An exchange states that a Choctaw princess died in the Indian Territory, the other day, at the great age of one hundred and fourteen years. She had thirteen great-great-grandchildren.

Medical and Surgical Journal.

THURSDAY, MAY 26, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 1 PARK STREET, BOSTON, MASS.

THE RELATION OF SOILS TO HEALTH.

SOMEWHAT more than a year ago Prof. Raphael Pumpelly appealed to the National Board of Health for aid in carrying out a series of investigations into the relations of different soils to the air and water currents passing through them. He proposed to study at the outset,—

(1.) The rates of flow of water and of air under given conditions.

(2.) The capacities of soils as filters in eliminating organic and inorganic substances from liquids.

(3.) Their capacities as filters in eliminating the living low forms of vegetable life, both germs and adult organisms, from ground-water and ground-air.

The National Board responded to Professor Pumpelly's request, and through its assistance the indispensable coöperation of a chemical collaborator, Prof. George A. Smyth, was secured, and the expenses of the experiments have been defrayed. Thus far the work has been confined to the soils and some other substances as filters in eliminating living low vegetable organisms from air and fluids, and in this direction only a beginning has been made. Though it is proposed to conduct the experiments as far as possible in the ground itself upon undisturbed soils, it was necessary to study first in the laboratory the behavior, in their pure state, of the separate constituents of soils, such as, quartz, sand, clay, loam, marl, loess, etc. A report of the work up to the present time appears as a supplement to a late Bulletin of the National Board of Health.

The question of ground-air and ground-water, of subsoil ventilation and drainage, as affecting the health of the inhabitants of the surface of any given territory, and especially of made-land, is an immensely important one, and, notwithstanding the researches of Von Pettenkofer, Wagus, Buhl, Buchanan, and other trans-Atlantic investigators, the suggestions of Dr. Bowditch, and the conclusions of Professor Nichols in his paper on *The Composition of the Air of the Ground-Atmosphere*, contributed to the Sixth Report of the Massachusetts Board of Health, the amount of exact knowledge on the subject is still small, and the attention given to it of late years is by no means proportionate to its importance. The value of pure atmospheric surroundings above ground is steadily preached, and widely heeded, but how few are the thoughts given to the atmosphere permeating the ground beneath our feet, and underlying our houses,—an atmosphere responsive to every

change in composition and equilibrium of the outer air, to every variation in rain-fall, and fluctuation of tidal movements. The changes affecting and produced by this ground-air are of an especial consequence to a people dwelling, as we in the Northern United States do, in houses heated for the most part by furnaces, whose air-chambers are too often fed by air drawn from the surface of the soil, and passing into the interiors through loosely-jointed wooden conduits resting upon the ground beneath a basement floor; such dispositions being calculated to make the character of the ground-air of even more consequence to the inhabitants of a house than that of the external atmosphere. The results of the experiments still being conducted at Newport will therefore be awaited with interest, and we trust that definite and reliable conclusions may be reached, at least on some of the vital questions involved. Time and money will be well spent if answers can be given to two questions which are proposed for resolution: (1.) To what extent various soils are capable of eliminating the injurious properties contributed to ground-water by the more usual sources of pollution. (2.) To what extent different soils are able to filter the injurious properties out of the air passing through them. The experiments proposed embrace, therefore, in a word: (1.) The action of soils or of artificial filters as filters for air or gases generally. (2.) Their action as filters for water and other liquids.

From the results of preliminary experiments already completed, the reporter concludes that it appears very clearly that sand interposes absolutely no barrier between wells and the bacterial infection from cess-pools, cemeteries, etc., lying, even at great distances, in the lower wet stratum of sand. And it appears probable that a *dry gravel* or possibly a *dry very coarse sand* interposes no barrier to the free entrance into houses built upon them of these organisms which swarm in the ground-air around leaching cess-pools, leaky drains, etc., or in the filthy made-ground of cities; and that a house may be built on a thoroughly dry body of sand or gravel, and its cellar may be far above the level of the ground-water at all times, and it may yet be in danger of having the air of its rooms contaminated by the germs from leaching cess-pools and vaults, for, if the drift of the leaching be toward the cellar, very wet seasons may extend the polluted moisture to the cellar walls, whence, after evaporation, the germs will pass into the atmospheric circulation of the house.

A further consideration of these questions will involve the determination of the influence of size of grains and character of interstitial passage; the influence upon the germs of length of time occupied in transit; of temperature and pressure, and of presence or absence of nourishment in the liquid; the determination also of the presence or absence of germs at various depths in different soils.

The important question, now in controversy, regarding the ability of germs or bacteria, or other particulate matters to disentangle themselves from a liquid and become suspended in the atmosphere, which has

an important bearing upon the relation between ground-water and ground-air, will likewise be investigated.¹

THE ARRANGEMENTS FOR THE CENTENNIAL ANNIVERSARY OF THE MASSACHUSETTS MEDICAL SOCIETY.

THAT the advisability of departing from the usual routine, and substituting therefor a new and more varied order of exercises for the forthcoming meeting of the Massachusetts Medical Society, in which is celebrated its centennial anniversary, has been sufficiently appreciated by the committee of arrangements is abundantly evidenced by the programme already issued, a copy of which is given in this number of the JOURNAL.

As will be seen by reference to this programme, the time at the disposal of the Society has been so divided among the various subjects of interest as to enable members to include the whole or to select such as may be most to their individual taste, and the arrangements made include ample provision for the convenience of the visiting members, and for passage from point to point.

Members taking the special train on the Boston and Albany railroad from Boston on the morning of the first day will be met at the Brighton station by a marshal, who will conduct them to the Abattoir, where arrangement has been made for a thorough exhibition of the buildings, and of the processes of slaughtering and rendering therein conducted. From the Abattoir coaches will run to Cambridge, arriving in time for the centennial address by Dr. S. A. Green in Sanders Theatre.

Visitors who prefer devoting the morning to Cambridge, will find, on arriving at Harvard Square, a guide who will direct them to the various points of interest, including the Museum of Comparative Zoölogy, founded by Louis Agassiz, and now containing the most complete collections illustrating the subject to which it is devoted in this country; the Peabody Museum, filled with objects of interest to the student of American archaeology and ethnology, among them large collections of prehistoric crania, specimens of the implements of extinct American races, and models of their dwellings; and the Gymnasium, the gift to the university of Augustus Hemenway, probably the most complete in all its appointments of any building devoted to similar purposes in this country, and especially worthy of a visit, since it provides so thoroughly for that perfection of physical training, the value of which can be perhaps best appreciated by the physician.

Through the courtesy of the president and corporation, receiving the society as guests of the University, an unusual opportunity is afforded for visiting these institutions, and also the Botanic Gardens, the Library, recently enlarged, and Memorial Hall.

Following the luncheon in Memorial Hall, speedy

conveyance is provided to Rowe's Wharf, whence the steamer starts for a harbor excursion, including a landing and lunch at Nantasket, all of which, if the weather is propitious, cannot but prove enjoyable.

Through the courtesy of the trustees of the Art Museum, an especially favorable opportunity is afforded for visiting the museum in the evening; the reception tendered will be a purely informal one, the attendance of ladies is requested, and members who have participated in the harbor excursion will return in ample time to find their way to the museum by the hour appointed, and that the day may be "in fair proportions fully rounded out," the reception at the Art Museum will be followed by a reception at the house of the president of the Society, Dr. Henry W. Williams.

On the morning of the second day, in addition to the usual visits to the various hospitals and museums in the city, the Art Museum, Trinity Church, and the Massachusetts Institute of Technology will be open to the members of the Society and its invited guests, and there will be also, as an especial feature of the meeting, a historical exhibit in Horticultural Hall. This exhibit will include valuable medical books, many of them of great antiquity and rarity, old and new surgical instruments, and a display in materia medica and pharmacy, the basis of which is furnished by the cabinets of the medical department of Harvard University and of the Massachusetts College of Pharmacy.

The committee of arrangements of the Society is to be congratulated upon its programme, and should the members show as much zeal in availing themselves of the privileges offered as the committee has shown in providing them, the centennial anniversary can hardly fail to prove an occasion of equal profit and enjoyment.

TWO IMPORTANT PRIZES.

WE take much pleasure in calling the attention of our readers and of the general medical public to the announcement of the terms of two of the most important prizes offered in this country to the profession.

The Warren Prize Committee, which is composed of the physicians and surgeons of the Massachusetts General Hospital, *ex officio*, offer a premium of \$400, the largest medical prize offered in this country for general competition, for the best dissertation worthy of a prize upon Chronic Bright's Disease (parenchymatous and interstitial nephritis): The Nature and Mutual Relations of the Circulatory and Secretory Organs. This is a triennial prize, and will be awarded in 1883; none of the essays offered in 1880 were found worthy of an award.

The other prize to which we direct the attention of those whom it may concern is that offered by the Alumni Association of the College of Physicians and Surgeons of New York. The precise terms of the prize will be found in the committee's announcement in our advertising columns. The amount of the award is \$500; competition is restricted to graduates of the College of Physicians and Surgeons; the sub-

¹ The microscopic examinations involved in the studies hitherto undertaken have been for the most part made by Drs. Steinberg United States Army, and W. S. Bigelow, of Boston.

ject of the essay is at the option of each competitor, the committee only stipulating that the essay present sufficient experimental or clinical observation to form a useful contribution to medical literature.

MEDICAL NOTES.

— A young girl, a domestic in a family in Brookline, was attacked with small-pox during the past week. She undoubtedly contracted the disease from her brother, whose case was recently reported from Brighton.

— The annual report of the Zoölogical Society of Philadelphia gives the report of Professor Henry C. Chapman, the prosecutor, of the causes of the fifteen deaths that have taken place during the year. A *siren lacertina*, an ant-eater, a porcupine, and a kangaroo died without organic disease, a moor monkey and a howling monkey of phthisis, a howling monkey and a porcupine of heart disease, a cassowary of dysentery, a howling monkey of inflammation of the intestines, a phalanger of peritonitis, a sea lion of tuberculosis, a phalanger of tuberculosis, a kangaroo of hydatids of the liver, and a *menobranchius lateralis* of tania and peritonitis.

— Among the French Canadian colony at Adams, in the western part of this State, there is an epidemic of small-pox of a severe and malignant character. There have been forty cases and eight deaths up to the moment of writing. The first case occurred in a woman occupied as a rag-picker, and was not immediately recognized, there being a great deal of measles about the town.

WASHINGTON.

— At two of the tri-weekly meetings of the Anthropological Society, April 12th and 26th, Dr. Robert Fletcher, U. S. A., gave an interesting account of the most recent investigations into the origin and nature of *rondelles*, in a paper entitled *Prehistoric Trephining*. He began by referring to Prunières's researches in the dolmens of La Lozère, and his description of the cranial amulets as found there. The determination of the fact that these *rondelles* are connected with a surgical operation was brought out by the investigations of Broca, who cooperated with Prunières in this field of study. He showed that in the numerous skulls from which portions had been removed after death (*post-mortem trephining*) there was in every case a fragment of the hard ivory-like edge indicating *electrization during life*. He inferred that an operation must have been performed, probably to relieve disease, and that after death *rondelles* or amulets were taken from the skulls of those who had survived the operation, and were consequently possessed of peculiar qualities; these *rondelles*, like the apertures in the skulls, always presenting one edge that was smooth and polished as consequent upon a process of natural electrization, the well-defined beveled edges at the expense of the outer table and the sharp scratches showing where the tool had slipped, preclude

their consideration as the result of wounds or other injuries, but confirm the opinion that they were made by the aid of a special instrument; the appearance of the parts operated upon and of the adjacent sutures in the skulls found, all seem to indicate that the operation was performed at an early age. At this point an interesting question was raised as to how far race characteristics may influence the ability to resist the after effects of surgical operations. Then came an inquiry into the character of the instrument used; it was not the trephine as we know it, not a boring instrument, nor a flint saw, but probably a *scraper*, such as is used to-day in the South Sea Islands. Broca imitated exactly the condition of the parts by the use of a piece of broken glass, in four minutes, on a child's skull, and by the use of a piece of flint from Cro Magnon, in eight minutes, on the skull of a two months' old puppy. The summary of Broca's conclusions as to the purpose of this trephining was, in effect, that the operation was not performed for fracture or disease of the bone, but for simple or epileptic convulsions. Here the use in historic times of powdered bones in epilepsy, and of exorcisms on the person possessed with a devil, comes with peculiar aptness to our minds. Among the South Sea Islanders and Arabs of Algeria this operation to-day lets out the evil spirit.

The discussion of the extent and range of this singular custom formed an interesting part of the paper; researches in France seem so far to prove the most prolific, and no well-authenticated cases appear to have been discovered of earlier date than the polished stone age. Some twenty specimens exist where the outer table alone was removed by scraping. Dr. Fletcher refers to a little work, now excessively rare, published in Lyons, 1603, a treatise on epilepsy by Jehan Taxil, where the writer prescribes the scraping away of a portion of the outer table of the skull, sometimes also removing the inner table by the *exfoliative trephine*. In Germany a few examples have been met with, but Dr. Fletcher questions the probability of the skulls found in the Sedlee (Bohemia) ossuarium as belonging to this class. Russia, Italy, and Denmark have all furnished specimens for this interesting study. In America the Inca skull brought from Peru by Squier is our only evidence of prehistoric trephining, and this differs very materially from those described.

The paper concluded with a description of the method of trephining now used by the Kabyles of Algeria. The conclusions reached are that these perforated neolithic crania establish the existence of a custom of trephining, performed on both sexes, and generally at an early age, probably for disease of the brain, injury of the skull, epilepsy, or convulsions; that it was performed by scraping, possibly by a series of punctures; that fragments were removed, after death, from the trephined skull, each fragment to show a portion of the edge of the part operated on, and to be worn as an amulet in protecting the individual from the disease or injury for the relief of which the operation was performed.

This brief notice gives but an inadequate idea of the interest and value of a paper which it is hoped will soon be published, with the illustrations which accompany it.

Miscellany.

LETTER FROM VIENNA.

NOTES ON THE SURGICAL CONGRESS AT BERLIN.

MR. EDITOR,—Having recently attended the annual meeting of the Society of German Surgeons at Berlin, I will endeavor to call attention to a few of what seemed to be the most interesting and important subjects discussed, without attempting to give anything like an account of the very interesting four days' session.

Four papers relating to joint disease, and especially treating of their connection with tuberculosis, were read by Professors König and Hüter, and Drs. Mikulicz and Lönneburg. These papers led to a very interesting discussion on the recent observations on joint tuberculosis, and their effect on the methods of treatment. All agree that tuberculosis often does occur in cases of chronic inflammations, without (apparently) being present in other organs; that the patients so affected may afterwards die of general tuberculosis; and, finally, that there are cases of joint disease and caries where no tubercle can be found.

On the other hand, it seems to be still undecided at what stage of the disease tubercle first appears when present, and what weight its presence should have in forming a prognosis. It is observed that miliary tubercles may be present in the granulations of wounds after any long suppuration, as, for example, after complicated compound fractures, about sequestra, etc., and in these cases, as a rule, their presence does not render the prognosis especially unfavorable. In other cases, however, soon after their appearance in joints, tendon sheaths, or elsewhere, there follows, more or less rapidly, general infection and death. Thus the theory has been advanced that where the tuberculosis is local and the diseased tissues can be removed, it should be treated like any malignant growth, and excised as soon as possible, in the hope of checking its further progress.

In this hope Professor König has been operating, and he gives, as the result of his operations performed comparatively early in joint disease, a mortality from subsequent tuberculosis and other wasting diseases of twenty per cent. This is for a period of three and a half years; adding another year's results to this the mortality becomes twenty-five per cent., which is exactly the same result observed by Billroth in an enormous series of cases, covering a period of sixteen years.

The experiments on animals have been very unsatisfactory. Rabbits can be inoculated with tuberculous abscess membranes, and tuberculous disease of the joints produced, but other, indifferent substances have the same effect, and experiments have as yet shown but little.

Professor Tiersch, in summing up, remarked that much work had been done in this department of surgery of late, but that the subject was still in a confused, uncertain condition, many most important questions remaining to be answered through long and careful experiment and observation.

Dr. Mikulicz' paper on Iodoform as a Dressing in Joint and Bone Tuberculosis, was a short but interesting report of a series of thirty-six cases occurring in Professor Billroth's clinic, where this treatment was used. This series includes cases of disease of nearly all the large joints, the hip, knee, ankle, elbow, etc., and many chronic abscesses connected with diseased bone. This form of treatment was first proposed by Professor Mosetig-Moorhof, of Vienna, where the method has been quite generally adopted with the most satisfactory results. The use of iodoform as a dressing of unhealthy wounds has long prevailed, but now it is used somewhat differently, and much more thoroughly.

In joint diseases, caries, cold abscesses, etc., the diseased bone, fungous granulations, and other abnormal tissues are removed with knife or curette, the cavity thoroughly washed out with carbolic or thymol, and *entirely filled* with iodoform. A usual dressing of gauze and Mackintosh is then applied over all, and the part immobilized by means of an organic bandage. Unless the discharge soaks through the dressing it is not removed for one, two, or even three weeks.

The results obtained have been remarkably good, cases having been cured that would have been amputated under the older methods of treatment. The iodoform diminishes the secretion, prevents its decomposition, and prevents the formation of tubercle in the granulations or destroys them if they are already present. This specific local action on tuberculous granulations has been repeatedly observed, portions of the tissues being examined microscopically before and after its use. This may easily be observed where the granulations have not been first removed.

This observation of the action of iodoform upon tuberculous masses with which it is in contact led to the trial, in Professor Billroth's clinic, of injecting an ethereal solution of iodoform into joints in the early stages of fungous inflammation, and into other suspected tuberculous swellings. A solution of iodoform in ether, one part to five, is injected with a hypodermic syringe directly into the joint or tumor in several places, one or two syringes full being used. The ether is immediately absorbed, and the iodoform is left in substance in contact with the diseased tissues. This method has been too short a time in use to allow judgment to be passed on its merits, but in the large number of cases where it has very recently been tried, no inflammation or irritation has followed, and in some cases there has been a decided decrease in the swelling.

Iodoform is also used in all wounds connecting with the mouth, intestine, rectum, vagina, etc., in fact in all places where a disinfectant and antiseptic is needed where carbolic acid cannot conveniently be used. Thus, in recent tongue and partial larynx excisions, and in cancers of the mouth, iodoform has been used as a dressing, a piece of gauze plentifully sprinkled with the powder being packed against the wound. This completely checks all tendency to decomposition of the secretions, and no odor can be perceived, thus rendering unnecessary the hourly washing out with permanganate or carbolic solution.

Iodoform is apparently absorbed but little, and no toxic effects have been observed beyond a slight nausea in thirty-six to forty-eight hours in a few cases, even this symptom immediately disappearing.

Dr. Mikulicz described a series of experiments made

by him on the antiseptic action of iodoform. He found that when added to urine or solutions of animal matter it did not entirely prevent the formation of bacteria, but the solutions remained without smell or signs of decomposition. In blood the bacteria appeared in smaller numbers, and much more slowly, probably on account of the solution of a part of the iodoform present by the fatty matter contained in the blood.

Professor Gussenbauer spoke of nineteen cases in which he had resected the larger joints for disease, the after-treatment being with iodoform. In one case the whole calcaneus was removed, and the cavity filled with two hundred grammes of iodoform. The dressing was changed but once a month, and the wound healed. He considered his results in these cases much better than could have been expected with the usual treatment.¹

Professor Langenbeck spoke of amputation of the tongue, recommending the use of the thermo-cautery after the ligature of one or both linguals. The mouth is drained by large tubes inserted, through the wounds made by tying the linguals, by means of a large trocar.

Professor Langenbeck also showed a patient on whom he had operated some time previously for recurrent epithelioma of the forehead, removing a piece of the diseased skull and dura mater ten centimetres in diameter, together with a piece of pia mater and adherent brain substance two centimetres in diameter. The wound was healed with the exception of a small, healthy granulating surface in the centre of the cicatrix.

Dr. Martin, of Berlin, reported a series of twelve cases of cancer of the uterus where he had performed vaginal hysterectomy. In four of these cases he was not able to complete the operation on account of firm adhesions to neighboring parts. Of the other eight cases six recovered. Patients were shown who were operated upon in October and November last, where there was, as yet, no recurrence of the disease.

This operation has now been performed in Germany about fifty times, with a mortality of twenty-five per cent.

Dr. Gluck, of Berlin, showed two dogs in which he had removed bladder, prostate, and penis, both having made good recoveries. The ureters were brought out through the abdominal wall. He has performed this operation on dogs many times, always with success; when, however, he attempted to modify the operation by turning the ureters into the rectum the dogs always died from entrance of faeces into the peritoneal cavity.

Dr. Gluck also showed a hen, three centimetres of whose sciatic nerve had been excised, and a corresponding piece from another hen had been put in its place. This transplanted piece had been removed eighteen hours previously, and had been kept in a warm salt solution. At first there was total paralysis, but when exhibited, six weeks after the operation, she could use the leg almost as well as ever.

Dr. Mikulicz described a new osteo-plastic resection of the ankle, showing his patient. The operation is as follows: an incision is made through the sole of the foot from a little in front of the tuberosity of the scaphoid to a point just behind the tuberosity of the fifth metatarsal bone. From the ends of this incision others are made to the two malleoli, and their ends connected by a horizontal incision on the posterior

surface of the leg. All these incisions are quite to the bone. The foot is then disarticulated at the ankle-joint from behind, the astragalus and calcaneus freed from the soft parts on their dorsal surfaces, and removed by disarticulation at Chopart's joint. The malleoli and the posterior surfaces of the scaphoid and cuboid bones are then squarely sawed off, and the foot flexed until the sawed surfaces are opposed. Thus the foot is brought into a perfect equine position, the toes pointing in the same direction as the axis of the leg. In the present case the wound united by first intention, and when bony union was sufficiently good the patient was taught to walk, the toes bending at right angles to the metatarsals. Before the operation the patient had not walked for four years, and now, six months after the operation, he can walk without a cane, and works daily in the forests as a wood-chopper.

The three tumors of the pylorus recently removed by Professor Billroth were shown, and the cases reported.

Dr. Rydygier, of Kulm, also showed a pyloric tumor, removed a short time before with fatal result. In this case catgut sutures were used.

Dr. Madelung, of Bonn, read a very thorough paper on Extirpation and Uniting of Intestine. A large number of preparations from dogs were exhibited, showing the advantage of the Lambert over the Jobert (or invagination) method. His experiments also show that when the mesentery has been separated from too large a portion of the intestine, the nourishment through the intestinal wall is not sufficient, and the intestine becomes necrosed. Hence he advises that in ovariectomies, etc., where a considerable portion of the omentum is adherent, and must be tied, the corresponding portion of the intestine be excised, and the ends united. He has collected forty-nine cases of excision of portions of the intestine, with thirty-six recoveries. These operations were nearly all performed by German surgeons, and do not include the recent stomach extirpations or Koeberle's case, where over two metres of small intestine was successfully removed.

A discussion followed over the relative merits of silk and catgut for sutures in wounds of the intestinal tract. Silk was considered as much more suitable and safe by the majority of the speakers. S. J. MIXTER.

LETTER FROM LEIPSIK.

VETERINARY CLINIC OF LEIPSIK UNIVERSITY.

Among the numerous buildings belonging to the Medical Department of Leipzig University is one with a sign before it, stating that "Here are received, daily, animals of all sorts which are in need of medical attention." They can be brought to the Policlinic, or enter the hospital as patients.

A few inquiries of its enthusiastic director, Prof. Dr. Zürn, proves the institution to be not only interesting to horse doctors but to medical men in general. Its intention is not only to teach the diseases common to birds, dogs, horses, cattle, sheep, etc., but also to afford an opportunity to observe those which are transmitted from animals to men. Among those which are, perhaps, best illustrated are the diseases arising from the eating of infected meats.

From time to time trichinae are found, but the Germans claim to discover these chiefly among American hams.

¹ The cost of iod. form here is about five dollars per pound, much less, I think, than in America.

Tape worms are of very frequent occurrence in dogs, and specimens are shown, colored with carmine, and spread between two plates of glass, giving an excellent opportunity to observe their development and various segments up to maturity. The *echinococcus* is also preserved in a completeness in which one rarely has an opportunity to observe it in man, not only the cysts being shown, but also the intermediate forms, as they have been obtained from animals. There is also an opportunity from time to time to see several varieties of parasites, which are transmitted from animals to men.

The institution undertakes not only to treat animals, but also to make autopsies upon those that die in the hospital, and those that are brought from elsewhere for post-mortem examination.

Some pathological processes, as for instance that of arthritis, are beautifully illustrated by specimens in the museum, and from time to time interesting specimens are sent to the Pathological Institute of the Medical School for demonstration to the students.

Among the operations which are performed is that of tracheotomy, which is accomplished by the plunging of a sort of curved trochar into the trachea and the insertion of a tube. After the operation the animals almost universally do well, since the cases are not complicated by a diphtheritic process, as they usually are in man.

Inflammation of the leg of a horse is most effectively treated by inclosing the leg in a rubber, like the leg of a pair of trousers, and then flooding it continually from the water pipes, by fastening a hose filled with small holes around the upper part of the horse's leg. Thus the constant flow of water cools the leg efficiently, and the director says this plan accomplishes vastly more than ice-bags. The institution also provides conveniences for the propagation of vaccine lymph.

During the last year have been sent to the hospital for treatment 1655 animals, of which number 357 were received into the hospital, and 1298 were treated at the Polyclinic. The charges for care, treatment, and medicine for a horse amount to less than 75 cents daily, unless he has the colic and requires night attention, when the charges may reach \$1. The expense for a cow is between 40 cents and 50 cents daily, and for a dog from 20 cents to 25 cents per day.

In addition to the facilities for the treatment of animals are also those for medical investigations conducted upon animals, and the institution is utilized from time to time for such purposes.

PHAGEDENIC ULCERS TREATED BY INJECTIONS OF NITRATE OF SILVER.

A method of treatment practiced by Professor Karl Thiersch, of Leipzig, upon several cases of phagedenic ulcer, has produced excellent results. A solution of nitrate of silver one part to water 1000 parts is injected subcutaneously about the ulcer. The points of injection are separated from the edge of the ulcer, and from each other about three eighths of an inch, and perhaps a drachm of the solution is injected at each point. The ordinary subcutaneous needle is used with a syringe holding about an ounce. One case was that of a woman with a phagedenic bubo of the groin. The ulcer was about three and a half inches wide by about five inches long. The edges were indurated, and the integument was undermined by the ulcerative process. The ulcer had previously been curetted and treated

with various dressings, but without success, since the ulcerations continually extended. The patient was chloroformed, and the injections were made all about the edges of the ulcer, at a distance of one centimetre. Slight inflammation followed. Soon the edges of the ulcer became adherent to the parts below, and the process of cicatrization began. The injections were several times repeated. Two months later the patient was shown in the clinic with the ulcerated surface fully healed.

A second case was that of a man who had lived a good many years in India. While there several fistulous tracts developed themselves about the folds of the nates. The disease was supposed to be syphilis and the patient was treated specifically. In India, London, and Germany the case had been treated for several years as one of syphilis, and everywhere the patient was given iodide of potash. There was no improvement, however, but the fistulae extended until the folds of the nates and the tissues about the rectum, and the inner and posterior surfaces of the thighs were involved in a cicatrix, filled with fistulous tracts. Motion of the legs had become difficult and it was a question if the hip-joints were not becoming involved in the disease. When the patient came under Professor Thiersch's care the iodide of potash was discontinued. Injections of the solution of nitrate of silver were made about each of the fistulous openings, and into some of the longer fistulae was injected a solution of nitrate of silver one part to ten parts of water, but the injections about the fistulae was one to one thousand parts, as in the other cases. During the months succeeding, the injections about the fistulae were repeated three times. After each injection the patient's temperature rose to 39.6° C., and the patient lost all appetite, but after two days the temperature became normal again. Six weeks after the first injection the patient was shown vastly improved. His appetite, which had been very poor, became good. He could move his legs very much better. The fistulae had many of them closed, and the local improvement was very marked.

Appearances seem to indicate a speedy and complete recovery. Both of these cases are especially interesting from the obstinacy with which they have resisted other treatment, and the rapidity with which their condition has been changed by the injections of nitrate of silver.

FRACTURED PATELLA TREATED BY MALGAIGN'S HOOKS.

Two cases of fractured patellae have recently been treated by Professor Thiersch by the application of Malgaign's hooks. In one case there was a large effusion into the knee-joint. The joint was punctured with a common trochar under antiseptic precautions, and the fluid, which was partly clotted blood and partly serum, was removed. Three weeks later all swelling and inflammation had disappeared. The fragments of the patella were separated from each other about three fourths of an inch. About this time Malgaign's hooks were applied and the fragments were drawn into close apposition. The hooks were allowed to remain in place four weeks. During this time there was no inflammation, and no pain except a little the first two days. On removal of the hooks the bones separated from each other about one fourth inch, and there was found to be no bony union, but the fragments were separately movable. A second case of fractured patella, in which

there was slight effusion, was also treated by the insertion of hooks, which remained in place four weeks. On their removal there was no bony union.

If bony union of fragments of a patella is to be secured by the application of apparatus it would seem that it would be secured by the use of Malgaign's hooks, but neither of these cases showed more successful results than those treated in the Massachusetts General Hospital by the attachment of strips of adhesive plaster above and below the knee, drawing the fragments of the patella together. The common idea, however, that hooks are barbarous, would not seem to be borne out by these cases, since in each case the patients said the pain was but slight for from one to two days, and in neither case was there inflammation or suppuration.

SPINA BIFIDA TREATED BY IODINE INJECTION.

A child nine months old was shown by Professor Thiersch, that had been treated and apparently cured of a tumor such as commonly accompanies spina bifida. It was born with a tumor about three inches in diameter, located in the lumbar region. This was treated with injections of iodide, the formula being iodide of potash, two parts; iodine, one part; and water sixty parts. The first injection was made when the child was six weeks old, fifteen minims being injected. The injection was repeated twice each week, until nine injections had been given. Very little disturbance followed the injections. Seven months later the child was shown, and the tumor had contracted to one half its original size. The mass which remained was tough and unyielding, and seemed to be composed wholly of cicatricial tissue. The child was very active, seemed perfectly healthy, and all its movements were normal.

DUDLEY P. ALLEN, M. D.

INTRA-UTERINE POST-PARTUM INJECTIONS.

MR. EDITOR.—I have read with much interest the article by Dr. Edward J. Forster in the *JOURNAL* of May 12th, on intra-uterine injections after confinement, but would suggest, however, that the necessity of this procedure would less often occur if it was customary to express the blood clots from the uterus the first two or three days after delivery, as is practiced in Vienna by Dr. Pawlik, Prof. Carl Braun's assistant.

The Credé method for the expression of the placenta is now universally used, and I think that its adoption for the expression of blood clots after delivery would remove in a great measure one of the commonest causes of septicæmia. HAROLD WILLIAMS, M. D.

—The seventy-fourth annual commencement of the College of Physicians and Surgeons was held on the evening of the 13th of May at Steinway Hall, when the degree of doctor of medicine was conferred upon one hundred and twenty graduates. The five hundred dollar Cartwright prize of the Alumni Association was awarded to the essay of Dr. Henry, of Philadelphia, on The Hematoeycometer in the Examination of Blood and Milk Globules, and the Joseph Mather prize of one hundred dollars to that of Dr. Etienne Evetsky, of New York, on The Physiological and Therapeutic Effects of the Scabæ Cornutum. There was no valedictory by a member of the class, and the address to the graduates was delivered by the Rev. Wm. M. Taylor, D. D.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 7, 1881, TO MAY 20, 1881.

HARVARD, V., captain and assistant surgeon. Relieved from duty at Presidio del Norte, to proceed to Fort Concho, Texas, await there the arrival of Captain Livermore, corps of engineers, and report to him by letter. S. O. 63, Department of Texas, April 28, 1881.

MAUS, L. M., captain and assistant surgeon. Relieved from duty in Department of Dakota, to proceed to Washington, D. C., and report in person to the surgeon-general. S. O. 104, C. S., A. G. O.

SHANNON, W. C., captain and assistant surgeon. Now awaiting orders in New York city, to report in person to commanding general, Department of the Platte, for assignment to duty. S. O. 104, C. S., A. G. O.

SHUFELDT, R. W., first lieutenant and assistant surgeon. Relieved from duty in Department of the Platte, to proceed to Washington, D. C., and report in person to the surgeon-general. S. O. 104, C. S., A. G. O.

CUNNINGHAM, T. A., first lieutenant and assistant surgeon. Now awaiting orders at Danville, Va., to report to commanding general, Department of the South, for assignment to duty. S. O. 104, C. S., A. G. O.

PERLEY, H. O., first lieutenant and assistant surgeon. Relieved from duty in Department of Dakota, to proceed to Detroit, Mich., and report, on arrival, by letter to the surgeon-general. S. O. 104, C. S., A. G. O.

COCHRAN, J. J., first lieutenant and assistant surgeon. Relieved from duty at Fort Lewis, Colo., and assigned to duty at Fort Garland, Colo. S. O. 86, C. S., Department of the Missouri.

BUSHNELL, G. E., first lieutenant and assistant surgeon. To proceed to Fort Yates, D. T., and report to the commanding officer of that post for duty. S. O. 81, Department of Dakota, May 6, 1881.

BIRMINGHAM, H. P., first lieutenant and assistant surgeon. To proceed to Fort Riley, Kans., and report to Major E. B. Beaumont, Fourth Cavalry, for duty with troops about to take the field in Colorado. S. O. 90, Department of the Missouri, May 7, 1881.

KEENEY, C. C., lieutenant-colonel and surgeon. When relieved by Surgeon Bailly to await orders at San Francisco, Cal. S. O. 112, C. S., A. G. O.

BAILLY, E. I., lieutenant-colonel and surgeon. To report in person to the commanding general, Military Division of the Pacific and Department of California, for assignment to duty as medical director of the Department of California, relieving Surgeon Keeney. S. O. 112, A. G. O., May 16, 1881.

MCPARLIN, T. A., lieutenant-colonel and assistant medical purveyor. When relieved by Surgeon Clements to proceed to San Francisco, Cal., and assume charge of the medical purveying depot in that city, relieving Captain Henry Johnson, medical storekeeper. S. O. 112, C. S., A. G. O.

TREMAINE, W. S., captain and assistant surgeon. His leave of absence on account of sickness, granted him January 20, 1881, from this office, further extended six months on surgeon's certificate of disability. S. O. 112, A. G. O., May 16, 1881.

PARZKI, J. H., captain and assistant surgeon. When relieved by Assistant Surgeon Cunningham to proceed to St. Augustine, Fla., and relieve Assistant Surgeon Gardner from duty as post surgeon. S. O. 45, C. S., Department of the South.

WORTHINGTON, J. C., captain and assistant surgeon. Assigned to duty at Fort Wayne, Mich. S. O. 86, Department of the East, May 14, 1881.

CLEMENTS, B. A., major and surgeon. To be relieved from duty at Willer's Point, N. J., June 1, 1881, to proceed to New York city, and assume the duties of attending surgeon there, relieving Lieutenant-Colonel McParlin. S. O. 112, C. S., A. G. O.

BILLINGS, J. S., major and surgeon. To proceed to London, England, as a delegate to the International Medical Congress, to meet there August next. He will also visit, on public service, such points in Holland, Belgium, Germany, and elsewhere as may be deemed necessary by the surgeon-general of the army. S. O. 110, A. G. O., May 13, 1881.

CUNNINGHAM, T. A., first lieutenant and assistant surgeon. Assigned to duty at Jackson Barracks, La. S. O. 45, Department of the South, May 14, 1881.

BRECHEMIN, L., first lieutenant and assistant surgeon. Relieved from duty at Fort Meade, D. T., and assigned to duty at Fort Yates, D. T. S. O. 81, Department of Dakota, May 10, 1881.

BENHAM, R. B., first lieutenant and assistant surgeon. His seven days' leave extended twenty-three days. S. O. 81, C. S., Department of Dakota.

Deaths reported 3173 (no report from New Orleans); 1251 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 796, consumption 404, lung diseases 347, diphtheria and croup 183, scarlet fever 154, diarrhoeal diseases 122, cerebro-spinal meningitis 88, small-pox 71, measles 47, typhoid fever 42, malarial fevers 27, erysipelas 24, whooping-cough 14, puerperal fever 14, typhus fever ten. From *cerebro-spinal meningitis*, Chicago 25, New York 22, St. Louis 11, Pittsburgh nine, Cincinnati five, Worcester three, Philadelphia, Milwaukee, and Lawrence two, Baltimore, District of Columbia, Buffalo, Springfield, New Bedford, Fitchburg, and Nantucket one. From *small-pox*, Philadelphia 35, New York 19, Chicago 11, Cincinnati two, Brooklyn, District of Columbia, Pittsburgh, and New Haven one. From *measles*, New York 15, Chicago and Baltimore nine, Brooklyn, Boston, and St. Louis three, Winchester two, Milwaukee, Providence, and Lowell one. From *typhoid fever*, New York 10, Philadelphia six, Brooklyn and Chicago four, Pittsburgh three, Boston, Cincinnati, Lawrence, and Holyoke two, Baltimore, District of Columbia, Buffalo, Milwaukee, Lowell, Malden, and Amherst one. From *malarial fevers*, New York 13, Brooklyn four, St. Louis three, Philadelphia, Chicago, and District of Columbia two, Baltimore one. From *erysipelas*, New York six, Philadelphia four, Boston three, Brooklyn, St. Louis, and Brockton two, Chicago, Cincinnati, Milwaukee, New Haven, and Lowell one. From *whooping-cough*, Chicago four, New York three, Brooklyn and Providence two, Baltimore, Lawrence, and Chelsea one. From *puerperal fever*, Chicago and New Haven three, New York and St. Louis two, Boston, Worcester, Fall River, and Newton one. From *typhus fever*, New York nine, Philadelphia one. The mortality from cerebro-spinal meningitis was 88 against 81 for the previous week.

Thirteen cases of small-pox were reported in Brooklyn, 23 in Chicago, one in Boston, one in Cincinnati, three in Pittsburgh, one in New Haven, one in Newburyport; diphtheria 24, scarlet fever 13, in Boston; scarlet fever 14, diphtheria 12, in Milwan-

kee; measles 26, röteln four, scarlet fever five, diphtheria two in Providence.

In 46 cities and towns of Massachusetts, with a population of 1,134,973 (population of the State 1,783,086), the total death-rate for the week was 21.09, against 20.99 and 22.39 for the previous two weeks.

For the week ending April 23d, in 149 German cities and towns, with an estimated population of 7,878,558, the death-rate was 27.7. Deaths reported 4198; under five 1837: pulmonary consumption 641, acute diseases of the respiratory organs 498, diphtheria and croup 166, diarrhoeal diseases 132, typhoid fever 65, scarlet fever 61, whooping-cough 51, puerperal fever 32, measles and röteln 27, typhus fever (Königsberg two, Stettin, Elbing, Thorn three, Tilsit, Bromberg, Berlin two, Frankfurt 12, small-pox (Benthen one, Munich, Berlin two, Aachen two, Essen) seven. The death-rates ranged from 15.3 in Lübeck to 41.2 in Münster; Königsberg 39.8; Breslau 32.7; Munich 40.9; Dresden 24.6; Berlin 26.7; Leipzig 26.5; Hamburg 26.4; Hanover 18.7; Bremen 26.4; Cologne 22.6; Frankfurt 21.3; Strasburg 25.9.

For the week ending April 30th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 21.2. Deaths reported 3089: acute diseases of the respiratory organs (London) 328, measles 83, whooping-cough 83, small-pox (London 70) 71, scarlet fever 60, fever 35, diarrhoea 32, diphtheria 11. The death-rates ranged from 12.8 in Leicester to 26.9 in Salford; Leeds 16.8; Birmingham 17.1; Bristol 21.6; London 21.8; Sheffield 22.5; Manchester 23.5; Liverpool 25.1. In Edinburgh 20.1; Glasgow 21.7; Dublin 30.7.

In the 21 chief towns in Switzerland, for the week ending April 30th, population 479,934, there were 38 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 18, diphtheria and croup four, whooping-cough three, measles two, typhoid fever two, scarlet fever two.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

CENTENNIAL ANNIVERSARY, MASSACHUSETTS MEDICAL SOCIETY.—*Programme for Tuesday, June 7, 1881.* Nine o'clock A. M.: The following departments of Harvard University at Cambridge will be open, and the officers in charge of them will be glad to receive the members of the Society between nine and eleven o'clock A. M.: Museum of Comparative Zoölogy, Peabody Museum of American Archaeology and Ethnology, Botanic Garden and Herbarium, Library, Gymnasium. Horse-cars leave Bowdoin Square, Boston, for Cambridge, every five minutes. The time required for the ride is thirty minutes. On arrival at Harvard Square, Cambridge, a police officer will be in waiting to direct members to such of the above points of interest as they may desire to visit. The Abattoir at Brighton will be open at nine o'clock, and the manager will be happy to explain, and practically demonstrate, the business carried on in that establishment. A special train will leave the Boston and Albany depot, corner of Beach and Albany Streets, for Brighton, at 8.45 o'clock A. M. Fare, fifteen cents. Coaches will leave the Abattoir at 10.25 o'clock, precisely, reaching Cambridge in time for the Centennial Address. Fare, fifteen cents. Eleven o'clock A. M., precisely: the Centennial Address, by Samuel A. Green, M. D., of Boston, in Sanders Theatre, Cambridge, Mass. Twelve o'clock, M.: The President and Fellows of Harvard College invite the members to take luncheon with them in Memorial Hall at twelve M. 12.45 o'clock P. M.: Horse-cars will leave Memorial Hall for Bowdoin Square, Boston, whence conveyances, free, will carry members of the Society to Rowe's Wharf, 340 Atlantic Avenue, Boston. Two o'clock P. M.: By invitation of the profession of Boston and vicinity, members of the Society will embark for an excursion in the harbor on the steamer John A. Andrew, leaving Rowe's Wharf, 340 Atlantic Avenue, at the above hour precisely. The steamer will reach Rowe's Wharf on its return at 6.30 P. M. 7.30 o'clock P. M.: The trustees of the Museum of Fine Arts, corner of Huntington Avenue and Dartmouth Street, will receive the members of the Society, with ladies, from 7.30 to nine o'clock P. M. 8.30 o'clock P. M.: The President of the Society, Dr. Henry W. Williams, will receive the members at his house, 15 Arlington Street, from 8.30 to 10.30 o'clock P. M.—*Programme for Wednesday, June 8, 1881.* Nine o'clock A. M.: There will be a comparative and historical exhibition of instruments, apparatus, books, and medicines, in the lower Horticultural Hall, 100 Tremont Street, Boston. From nine to eleven o'clock A. M. there will be operations and surgical visits at the Massachusetts General Hospital, in Blossom Street; at the Boston City Hospital, on Harrison Avenue; at the Carney Hospital, in Old Harbor Street, South Boston; and at the Children's Hospital, 1583 Washington Street. During the same hours, through the courtesy of the officers in charge, the Museum of Fine Arts, the Institute of Technology, the Museum of the Natural History Society, and Trinity Church, on Boylston Street; also the Warren Museum, at the Medical College, North Grove Street, and the Warren Museum of Natural History, 92 Chestnut Street, will be open to members of the Society. Eleven o'clock A. M.: The One Hundredth Annual Meeting of the Society will be held in Horticultural Hall, Boston. Order of proceedings: (1.) Reports and names of new and of deceased Fellows. (2.) Reports of committees. (3.) Introduction of delegates. Twelve o'clock M., precisely, the annual discourse, by J. Collins Warren, M. D., of Boston. The hall doors will be closed at twelve

o'clock, precisely, and will remain closed during the delivery of the discourse. One o'clock P. M.: The annual dinner will be served in the Music Hall. Fellows will enter by the Tremont Street entrance only, being called in order of seniority in Horticultural (upper) Hall, whence the procession will start.

JAMES C. WHITE, M. D., *Anniversary Chairman.*

No person will be admitted to the dinner without a ticket. The dinner ticket (not transferable) may be obtained on steamer John A. Andrew, on Tuesday, or in Lower Horticultural Hall, from nine to twelve o'clock, on Wednesday, on presentation of evidence that the dues for the current year have been paid.

NORFOLK DISTRICT MEDICAL SOCIETY.—At the annual meeting of the Norfolk District Medical Society, held on the 10th inst., the following officers were elected for the ensuing year: President, W. C. B. Fifield, M. D., Dorchester. Vice-President, T. H. Dearing, M. D., Braintree. Secretary, Reporter, and Librarian, Walter Channing, M. D., Brookline. Treasurer, N. Call, M. D., Roxbury. Commissioner of Trials, J. Steadman, M. D., Jamaica Plain. Censors, Drs. E. T. Williams, Roxbury, W. P. Bolles, Dorchester, G. K. Sabine, Brookline, O. F. Rodgers, Dorchester, W. H. Campbell, Roxbury. Councilors, Drs. S. E. Stone, Walpole, A. R. Holmes, Canton, W. S. Everett, Hyde Park, J. H. Gilbert, Quincy, J. W. Chase, Dedham, G. W. Fay, East Weymouth, U. O. B. Wingate, Wellesley, J. H. Streeter, Roxbury, H. G. Morse, Roxbury, J. S. Flint, Roxbury, R. Amory, Brookline, J. A. Winkler, Jamaica Plain, B. Cushing, Dorchester, G. A. Bragdon, Dorchester, J. S. Greene, Dorchester. Nominating Councilor, J. S. Flint, M. D.

DR. CALER C. FIELD died at his home in Leominster, May 6th, of pneumonia. In the death of Dr. Field the profession have lost an earnest, thorough, and conscientious member, and the community in which he lived will ever cherish his memory as that of a much honored and beloved physician. The funeral obsequies were observed at his residence May 9th, with impressive ceremonies. Members of the Worcester North District Medical Society, and others of the State Society, were in attendance.

SUFFOLK DISTRICT MEDICAL SOCIETY.—There will be a regular meeting at the hall, 19 Boylston Place, Saturday, May 28th, at seven and a half o'clock. The following papers will be presented: Dr. H. I. Bowditch, The Medical Education of Women: The Present Hostile Attitude of Harvard University and the Massachusetts Medical Society. What Remedy therefore can be Devised? Dr. B. Joy Jeffries, The Community's Control of Defective Vision. Supper at nine o'clock.

H. C. HAVEN, M. D., *Secretary.*

The Censors of the Suffolk District Medical Society will meet for examination of candidates for the Massachusetts Medical Society at 19 Boylston Place, June 2d, at three P. M.

BOOKS AND PAMPHLETS RECEIVED.—Medical Electricity; A Practical Treatise on the Application of Electricity to Medicine and Surgery. By Roberts Bartholow, M. D. With Ninety-Six Illustrations. Philadelphia: Henry C. Lea's Sons & Co. 1881. (A. Williams & Co.)

Original Articles.

HYDROBROMIC ACID: ITS ACTION ON THE CIRCULATORY AND NERVOUS SYSTEMS.

BY EDWARD T. REICHERT, M. D., NEWARK, N. J.

Late Demonstrator of Experimental Therapeutics and Instructor in Experimental Physiology in Post-Graduate Course in Medicine, University of Pennsylvania.

THE several papers which have been recorded on the therapeutical use of hydrobromic acid indicate that this new drug possesses sufficient promise to call for a close study of its physiological properties, and especially so because of the asserted similarity of its physiological action and that of the alkaline bromides, together with the noticeable absence of the disagreeable digestive derangements which are known to so often follow the extended use of the alkaline salts. In a review of these papers it is found that this agent was first employed by Wade, who states that it fully represents the action of bromine on the system, and that it modifies the action of both quinine and morphia on the brain, the same as the potassium bromide. These statements have been corroborated by other observers, some of whom have further claimed that its effects are more intense, but less permanent, than it lacks the action of the potassium bromide on the heart and muscular systems, that it has been used with marked success in the treatment of tinnitus aurium, supposed to be due to labyrinthine congestion, that it is a tonic to the digestive organs, and that it readily becomes decomposed in the stomach.¹

This is the sum of the knowledge we possess of the action of this acid on the economy, and it certainly is sufficient to indicate, if the above statements be true, that we have a valuable addition to our materia medica. In order, however, to conclusively determine whether the acid possesses the peculiar physiological properties of the alkaline bromides, the following investigation was made, and since the recognized therapeutical properties of the alkaline salts are conceded to depend upon their peculiar actions on the circulatory and nervous systems, my researches were confined to this special study. One difficulty, however, to contend with in a comparison of the actions of this acid and alkaline bromides is that no thorough manometrical study of the action of the latter has yet been made, and even the papers so far published present conclusions which are at variance on many points.

In my experiments on the *circulation* it was found that the *arterial pressure* was affected in one of three ways, evidently depending upon the dose given. Thus, after very small doses it was wholly unaffected or a slight rise, which was almost inappreciable, occurred. After larger doses the pressure generally fell a little (making a tracing similar to that produced by stimulating the cardiac inhibitory nerves), and was followed by a return to or above the normal, and if the arterial tension was increased above the normal, it frequently remained so for six, eight, or ten minutes. In experiments when the pressure did not primarily fall, it increased from the first, and usually equaled, when it reached its greatest height, about one sixth of the normal pressure. After very large or toxic doses, the

blood pressure fell from the first, and continued to sink until it reached zero. In animals with cut vagi nerves, doses which would cause a primary fall of pressure in normal animals would induce a rise, and it was also noticeable that the rise of pressure, as a rule, was more marked in animals thus operated upon. This clearly indicates that the drug exerts some action on the pressure through the vagi nerves. After isolation of the heart from any centric nervous influence by severing the vagi nerves and cervical portion of the spinal cord, essentially the same results followed as occurred in normal animals. This, therefore, shows that outside of the action on the vagi nerves, as just referred to, these changes in the arterial tension must be dependent upon the action of the acid on either or both the heart and vaso-motor peripheries. In order to determine if the drug had any effect on the latter, microscopical examinations of the web of the frog's foot were made, and it was found that the local application of the diluted acid caused a distinct capillary contraction. A marked pallor was noticed after the local application of the acid to muscular tissue, but just how far this was due to capillary contraction or to probable myosic coagulation is unknown; the same pallor was also noticeable in some instances about the lips and eyes of animals under the influence of toxic doses. I think, therefore, from the above results, that it is fair to conclude that the peripheral vaso-motor mechanism is stimulated.

When the drug is applied locally to the heart the cardiac power becomes at once diminished, and the pulsations are soon arrested.

It is evident from the above results that the rise of pressure was due to a stimulation of the peripheral vaso-motor mechanism, and the fall to a direct depressant action on the heart muscle. The reason why a rise of pressure occurred during a consentaneous depression of the cardiac power was probably and simply because of a comparatively more intense action on the vaso-motor peripheries, the diminished capillary lumen being sufficient to more than compensate for the diminished power of the heart.

The *pulse-rate* was not appreciably affected by very small doses. Larger doses sometimes caused a momentary slowing, with a diminution of the arterial pressure (making a tracing similar to that caused by inhibiting the heart), and after the subsidence of this inhibition the pulse, to a various extent, recovered, not, however, reaching the normal, and it then became slowly diminished; at other times a momentary rise occurred (accompanied by a consentaneous diminution of the arterial pressure, but differing in character from that above noted) which equaled about one tenth to one fifth of the normal in excess, and this rise was followed by a diminution equaling about one third to one half of the normal. The increase of the pulse-rate was marked by pulse-curves, which were lower and less abrupt in their line of ascent than those of the normal, and the diminished pulse-rate by curves which were higher and more abrupt in ascent. After large and repeated doses (thirty drops in dogs) the pulse-rate fell below, but remained near, the normal until after the second, third, or fourth doses, and it then either rapidly fell to zero, or rose very rapidly (in one instance from thirty-three to seventy-eight pulsations in forty seconds); or, in a third lot of cases it rose gradually to the normal (taking in one instance six minutes to do so), and sometimes continued to in-

C. Woods (Therapeutics, 1879, p. 333); Browne (British Medical Journal, 1877, ii. p. 13).

crease considerably. If the doses are still repeated in cases like the last two the pulse-rate may rise at every dose, being followed by a diminution, and finally, a last dose will cause it to rise to a considerable height, near which point it may remain a few seconds, when the heart fails and the pulsations become slowed and gradually diminish until death ensues; or, instead of the final injection causing such a very marked rise, it may so affect the heart that its movements are at once arrested. In these several instances the increased pulse-rate was always accompanied by a diminution of the blood pressure, deep and labored respirations, and often struggles, and the pulse-curves were equal to only about from one tenth to one eighth of the normal size.

After section of the pneumogastric nerves, no change from the above results occurred, except that the very transient inhibition of the heart immediately following an intravenous injection was not present. The same may also be said of the results of experiments made on animals with cut cervical spinal cords and pneumogastric nerves, by which the heart was cut off from impulses originating in or reflected from the nervous centres. It is obvious, then, that with the exception just made, the changes in the pulse produced by hydrobromic acid are due to a direct action on the heart, and that this action is one of paralysis is evident from the fact that the increased pulse-rate was accompanied by a diminished size of the pulse-curves and diminished arterial pressure (notwithstanding an attendant condition of capillary constriction). It is obvious, then, that the increased pulse-rate was not an evidence of cardiac stimulation, but of depression, and was no doubt, in a measure, but a compensating action of the heart in endeavoring to overcome by increased frequency of pulsation, the results of its diminished power. It has been further found that the heart is less irritable after death than normally, and that the exposed heart of the frog was paralyzed by a direct application of the diluted acid.

Upon the nervous system hydrobromic acid seems to act as a universal depressant, producing in frogs, in toxic doses, a diminution and final extinction of all reflex and volitional phenomena, and the early induction of narcotism. In dogs, cats, and rabbits the action on the brain is comparatively feeble, while the same is equally as true as regards the action on reflex and voluntary movements, although not so marked. In frogs reflex activity is slowly and gradually diminished until a certain period is reached, varying from seven to twenty minutes, when it suddenly and completely disappears, at which time neither mechanical stimuli, nor the strongest current obtained from a Léclanché cell and a Du Bois-Reymond induction coil would induce the least response. It was also noticeable that failure of reflex movements occurred first in the posterior extremities, and that after stimulus, when applied to them, would elicit no reflex response whatever, response would still be called forth by stimulus applied to the anterior extremities; and in several instances, not only were these movements present in the anterior extremities when they were stimulated, but also in the posterior, indicating that the cause of failure of reflex movements in the posterior extremities when stimulus was applied to them was on account of a paresis of either the sensory nerves or sensory portions of the cord. For the motor nerves and motor portions of the cord must be capable of transmitting impulses else reflex phenomena would

not have occurred in the posterior extremities in those cases where the anterior extremities alone were irritated. On account of the interest centred in these experiments, the results of one of them is given in detail:—

Experiment. Frog; normal. 1.53 p. m. Reflex action occurred in one and a half seconds after immersion of posterior extremities in a two-per-cent. solution of sulphuric acid; the frog's legs were then completely washed of the acid solution by a gentle stream of water. 1.55. Ten minims of hydrobromic acid, properly diluted, were injected into the posterior lymph-sac. 2.00. Reflex action, tested as above, occurred in two seconds, the frog's legs being washed as before. 2.05. No reflex movements occurred even after a minute's immersion of the posterior extremities; reflex movements occurred in the anterior extremities in three seconds after being dipped in the acidulated solution, and were accompanied by feeble reflex movements in the posterior extremities.

Although in my experiments with this acid voluntary movements were never observed to occur after the suppression of reflex activity, such as have been so frequently observed after poisoning with the alkaline bromides, yet the above result certainly indicates that the action of these two poisons on both reflex and voluntary movements is identical; and this has been found by further experimentation to be the case, for in animals in which the abdominal aorta were ligated for the purpose of preventing the access of poison to the posterior extremities, reflex movements failed in the unpoisoned limbs as soon as they did in the others, indicating that the failure of these movements must have been due to a direct action of the acid on the spinal cord. Farther, by applying a galvanic current to the exposed spinal cord in the dorsal region of poisoned animals, no movements occurred in the anterior extremities, but pronounced movements were induced in the posterior; certainly showing that the inability of the cord to convey impulses upward must have been due to a paralysis of its sensory portions, while the motor portions must still have been intact, as was evident by the contractions caused in the posterior extremities. It is obvious from this that the seat of reflex paralysis lies in the sensory (reception) portions of the cord, and that if the motor portions of the cord and motor nerves still remain sufficiently intact to convey impulses, after complete paralysis of the sensory portions of the cord, the possibility of the occurrence of voluntary movements, or at least of movements the impulses of which have their origin in the cerebral ganglia, is readily conceivable. And it is probable that with small doses such phenomena will occasionally occur. Whether the peripheries of the sensory nerves are affected or not early in the poisoning I have been unable to decide, on account of the early depression of the sensory portions of the cord; I, however, do not think they are, because in animals in which all the blood-vessels of the left leg were ligated it was found that the unpoisoned nerve failed to respond to stimulus just as soon as the other; but that they are ultimately affected seems proven by the fact that the local action of the dilute acid rapidly destroys their activity. The motor portions of the cord as well as the motor nerves are also depressed, as determined by definite strengths of electric currents, and are ultimately paralyzed—the former succumbing first; since the motor nerves will still transmit impulses even after a complete abolition

of the functional activity of the motor portions of the cord. Consciousness in the higher vertebrates was maintained until almost death ensued, although in frogs narcotism seemed early induced.

In the early part of this paper it was stated that it was claimed that the acid "possesses all the more valuable properties of the potassium bromide, but lacks its influence on the heart and muscular systems;" but whatever it may possess of the aforesaid valuable properties, it certainly does affect the heart the same as the potassium bromide, as has already been conclusively proven; it depresses the skeletal muscles and ultimately paralyzes them (as I have also satisfactorily decided, although it is here unnecessary to give the detailed results of this research), and acts on the nervous system markedly similar.

A summary of the conclusions drawn from the results of the present research is placed for the convenience of reference in a parallel column with the conclusions arrived at by the different investigators on the action of the potassium bromide, which represents the physiological action of the alkaline salts.

HYDROBROMIC ACID.

The Circulation: Arterial Pressure. The arterial pressure is unaffected by very small doses, or a slight rise occurs; moderate doses cause an increase from the first, or a diminution of pressure, followed by a return to or above the normal; large doses cause the pressure to fall, and if sufficient cause it to fall to zero.

The fall of pressure is due to a depression of the heart muscle.

The rise of pressure to a constriction of the vaso-motor peripheries.

Pulse. The pulse-rate is not appreciably affected by very small doses; moderate doses sometimes caused a momentary slowing by inhibiting the heart, the pulse then recovering to a variable extent, and being followed by a gradual fall; or, a momentary rise occurs accompanied by a diminution of arterial pressure, this being followed by a diminution to below the normal; or, after large and repeated doses the pulse falls below normal and then becomes exceedingly rapid, or becomes rapid from the first, or may be depressed from the first. All these effects being due to a direct cardiac action, with the above single exception. The increased pulse-rate being attended with a diminution of pressure and small pulse-curves.

Nervous System: Cerebrum. Consciousness in the higher mammals present until near death. *Spinal Cord.* The sensory portions of the spinal cord

POTASSIUM BROMIDE.

Arterial Pressure: Administered hypodermically it causes diminished arterial tension, with increased pulse frequency. Large doses paralyze the heart, and thus reduce arterial pressure (I. G. Schonten, *Archiv der Heilkunde*, xii., 2, 1871; Schmidt's *Jahr.*, Bd. c. liv.).

(See above.)

Vaso-motor peripheries irritated, causing constriction (Lewisky, *Virchow's Archiv*, Bd. xlv., p. 191; Amory, *The Phys. and Ther. Action of Bromide of Potassium*, Boston, 1872; Menriot, *L'étude de la Belladone*, p. 49; Saisson, Schmidt's *Jahr.*, Bd. cxliii.) This action on the capillaries has been denied.

Pulse. After slow intravenous injection of a two per cent. solution of the potassium bromide, the pulsations become slower and feebler, the blood pressure falls, and the heart is finally arrested. Hypodermically injected, the pulse-rate is increased with diminished arterial pressure and diminished pulse-curves. Large doses paralyze the heart (Schonten, loc. cit.; Eulenberg and Guttman, *Virchow's Archiv*, xli., 1867).

Cerebrum, Spinal Cord and Nerves. "The evidence is, I think, sufficient to prove that bromide potassium affects all parts of the nervous system of

are the first portions of the reflex apparatus to be paralyzed, and reflex paralysis is due to this cause. The motor portions of the cord are also depressed, as well as both the sensory and motor nerves.

Muscular System. The muscular system is depressed.

the lower animals, but that the cerebrum, the motor tract of the cord, and the efferent nerves are the last portions to be affected; that the most sensitive is the receptive [sensory] portion of the cord . . . and next to this are the peripheral ends of the sensory nerves." (H. C. Woods' *Therapeutics*, 1879, p. 825).

Muscular System. Depressed, (Papers Quoted.)

A MEMBRANE-LIKE AFFECTION OF THE BOWELS.¹

BY FRANCIS W. GOSS, M. D.

By the above title I refer to a disease which has been designated by a variety of names, among them, "Painful Affection of the Intestinal Canal," by Powell,² "Diarrhœa Tubularis," by Good,³ "Mucus Disease" by Whitehead,⁴ and "Membranous Enteritis" by Da Costa.⁵ The affection, though not remarkably uncommon, is not often described by medical writers or referred to in text-books. It is characterized by the discharge from the bowels of what appear to be membranes or skins, of varying size, in the form of shreds, strips, or tubes. This peculiar discharge is accompanied with uneasiness and discomfort, if not with actual pain. The malady is of long duration, the patients, during the period of weeks or months while suffering from the discharge, being invalids, often confined to the bed or house. They seldom so far recover as to be in robust health, and sooner or later are subjected to recurrences of the trouble with the accompanying physical weakness and suffering.

Powell, in 1818, appears to have been among the first of modern writers to have called attention to the disease. He describes the evacuations of his patients suffering from the affection to have "exhibited a large quantity of flakes mostly torn into irregular shapes, and appearing to have formed parts of an extensive adventitious membrane of no great tenacity or firmness." "In the first of the cases which came under my notice," he says, "this membrane was passed in perfect tubes, some of them full half a yard in length, and certainly sufficient to have lined the whole intestinal canal. In others, also, the aggregate quantity has been very large, and it has continued to come away for many days, but it has been in irregular, thin flakes of not more than two inches in extent." And he further adds, "The appearance which comes nearest to it, both in resemblance and situation, is the membrane formed in the trachea under croup." Powell observed four cases, all in adult females.

I have myself notes of the following cases, the first two of which have been under my observation a portion of the period of their sickness. They both occurred in ladies of more than ordinary intelligence, able to give an accurate account of their ailments.

⁵ Membranous Enteritis. By J. M. Da Costa, M. D. The American Journal of the Medical Sciences. October, 1871.

CASE I. Mrs. A., aged forty-three, nearly twenty years ago, and for several consecutive years, had frequent dysenteric attacks. During these years she occasionally noticed white, filmy patches, like bits of wet tissue paper, in the discharges. In October, 1870, she had what her physician called "a slow nervous fever," which confined her to her room for six months. In December of that year she first discovered an appearance like a tangle of white, wet string, perhaps a small cupful in amount, in the evacuations; after this for three months there was more or less membrane-like discharge nearly every day. In character it resembled flakes of cold, boiled starch, sometimes a mass of boiled macaroni pressed or flattened out of shape, at other times a lump of hardened jelly, and more often sheets or strips, skin-like, from three to six inches long. At times some were, perhaps, nine inches in length by two in width. Tubes were occasionally noticed of at least an inch in diameter. At intervals of months during several of the following years there was slight recurrence of the trouble for a few days, without causing special inconvenience to the patient. In 1879, after a feverish condition, she had a prolonged season of the membrane-like affection, continuing for two or three months, with an occasional cessation for a day or two. In this attack the discharge was not as abundant as formerly, nor in so large pieces. In January, 1881, after a season of unusual comparative good health, began another attack of the trouble which lasted eight weeks.

In this case there have not been any definite symptoms to herald an onset of the disease. It does not appear to follow a cold nor indigestion. At times it has seemed to the patient that the recurrences came after over-exertion, either physical or mental. They are always attended by a general nervous condition, "restlessness and fidgets," to use her expression, and by weakness and uneasiness in the stomach. In earlier years there was no marked dyspepsia, but there has been more of late. The kind of diet does not seem to make any difference. The peculiar discharges are not unfrequently painless, though sometimes attended with a cutting or tearing sensation, but are always followed by great prostration for an hour or more. There is no especial pain for the rest of the day. There is general tenderness over the bowels during the period of attack; pulse somewhat quickened at times, usually from 80 to 90; temperature not abnormal; appearance of tongue, gums, and lips not remarkable. In the morning the tongue is apt to be coated. Bowels habitually constipated. The patient thinks she has not averaged more than one spontaneous defecation a month for the past ten years. She uses daily injections of tepid water. When an attack is approaching enemata cause pain. Since the beginning of March of the present year she has been recovering from the last recurrence of the disease. She is, however, still weak; feels tolerably well if she keeps quiet. For the past ten years she has taken but few long walks. There has not seemed to be any direct effect from medication; many things have been tried. Recently the aromatic sulphuric acid appeared to agree with her as well as anything. Sedatives and anodynes have been given *pro re nata*.

CASE II. Miss B., aged fifty-six, has had gastric troubles for many years. She first noticed membrane-like flakes in discharges some fifteen years ago. In 1868 she was confined to her bed for six months; had

pain in bowels and all over body. Since the above date she has had long intervals of comfort, but has also suffered from recurrences, during which, every few days, she would have the membrane-like discharges of varying amount. Sometimes a similar discharge from the vagina has accompanied that from the bowels. The attacks last a number of weeks. The past winter they were of shorter duration, owing, she thinks, to keeping her bed and avoiding care. They are usually preceded by distress in the stomach, with nausea, and sometimes vomiting. There is not great abdominal tenderness nor very much acute pain, but at such times, and during the intervals even, there is obscure pain in lumbar regions and over sacrum. When the gastric disturbance is present she cannot eat, and when this is relieved a diet of soft food for a while suits best. She cannot eat meat at these times. Has what she calls "inward fever." She is habitually constipated, and suffers much from flatulency. Often uses injections of olive oil. The membrane-like discharges have frequently been a quarter of a yard in length, but have never been noticed to be tubular. At one time she thought she must have a tape-worm, such were the length and appearance of the discharges. Following an evacuation of normal feces there is some discomfort, and when the peculiar material is voided, to use her expression, "then, what is curious, I breathe freer." A cheerful and courageous disposition, quiet, keeping in bed, and freedom from anxiety and care reduce the trouble to its minimum. Medicine has not had much effect, excepting the comfort afforded by anodynes and sedatives.

CASE III. M., aged forty, a friend of the patient referred to in Case I., writes the following account of herself, which I give *verbatim*.

"It is between eleven and twelve years since I first discovered anything of a membranous character in the discharges, but they might have been of that nature a considerably longer time, as my health for many years previous had been very poor, having suffered very much before that time, as well as since, with my head, spine, stomach, and in other ways. There has been a combination of different forms and appearances in the discharge, one form looking like membrane, or skin, some pieces of which would measure six inches in length, and on being unrolled an inch or more in width, besides numerous smaller pieces. Some portions are a thick mucus, or viscid transparent substance, tubular in form, nearly as large as a pipe-stem, and from three to eight inches in length, some pieces having a dark-colored thread extending through the centre, which thread is almost as difficult to sever as a wire. Then, again, some portions look like a thick phlegm, are of irregular shape, perhaps two or three inches in length and one half inch in diameter, white, yellow, or brown, while still other portions have an appearance of albumen accompanied with white or yellow froth. A few times there has been as much as a gill of the unnatural discharge at one evacuation, but not many, I think, though sometimes the smaller pieces are so intimately mixed with the feces as to render it difficult to judge of the quantity. Excruciating headaches, to which I am very subject, are induced in various ways, but chiefly by nervous excitement or fatigue, and are succeeded by great distress and weakness of the stomach, which is followed by more copious membranous discharge. Since the first year, when I had several spontaneous discharges daily, composed almost entirely

of mucous and membranous matter, I have averaged not more than five or six spontaneous discharges in a year, and those were of an unhealthy nature, not affording much relief, being only a partial evacuation. Both pain and weakness follow the membranous discharges, and there is but very little of the time but that I have more or less of them."

CASE IV. A friend has furnished from his notebook a case related to him in 1836, as a comment on Good's description of the affection, by his teacher, in whose practice it occurred years before.

"S. C., female, had pain in pit of stomach and bowels, together with abdominal tenderness. Could not take even the lightest food without great pain. Discharges like skin in appearance. Took bitters with no great benefit. Relieved by ferri carb., a teaspoonful three times a day."

The clinical history of the malady has already been quite clearly indicated by the cases here reported. The patients are usually persons who have not enjoyed good health, but have for years suffered from headache, dyspepsia, constipation, and general debility. They are easily fatigued. Care or over-anxiety often precedes and seems to bring on an attack. Rarely is there a single one, but there are commonly recurrences at intervals of months or years. The period of suffering may extend over many weeks, and during this time there are frequent discharges of the membrane-like substance, even several times a day. The paroxysms are commonly preceded by a febrile condition, nervousness, uneasiness in the stomach, and sometimes by nausea and vomiting. Abdominal pain and tenderness are not usually very marked nor limited to any particular region, and the discharge is followed in some cases by a sense of relief. In the intervals between the recurrences of the attacks the patients are rarely restored to vigorous health.

The disease is most frequently observed among females. Whitehead states that of a hundred cases four only occurred in males. Of the seven cases reported by Da Costa, however, four were in males.

The results of microscopical and chemical examinations of the peculiar discharge are recorded by Whitehead and Da Costa; the microscope shows it to be composed of a transparent, amorphous, basement membrane having imbedded in it spherical cells, together with epithelial cells in various stages of development. Chemical analysis, according to Da Costa, shows the discharge to be composed largely of mucus or of a substance of identical chemical composition.

Specimens from the first two cases reported in this paper were submitted to Dr. E. G. Cutler for examination, who has kindly furnished the following report:—

"The specimens correspond perfectly with the description given by Da Costa in his article. They might be divided into two classes, pigmented and non-pigmented. The former represented by the specimens from Miss B., and the latter by those from Mrs. A. The gross appearances of the two sets of specimens differ somewhat from each other, the latter—those from Mrs. A.—being of a bright brownish color, and the different portions appearing more like cords or thin membranes rolled on themselves, and hence somewhat dense; while those from the other patient were whitish or grayish, translucent and gelatinous, suggesting slightly coagulated white of egg, and more disposed in

flakes or plates of some size. Microscopic examination, on the other hand, revealed little difference in the composition of the two sets of specimens; since they varied only in enveloping different amounts of pigment and other extraneous matter. They consisted of an amorphous, transparent, hyaline basement substance, here and there having a few indistinct fibrils and containing a considerable number of nuclei, and also rather granular, imperfectly or irregularly shaped cells, evidently epithelial, in no very large number. Addition of acetic acid gave the mucine reaction. In some of the specimens a good deal of pigment was found and some fat and small granules. Nothing like fibrine or blood was discovered. They evidently consisted of tough mucus entangling cells and foreign matters, such as pigment, small quantities of fat, and so forth, and the difference in color was due to the varied care with which they had been washed, or the difference in the media in which they were preserved."

Of the pathological anatomy of the affection almost nothing is known. As the disease is very rarely fatal the opportunities for post-mortem examinations are few. Many of the names which have been given to it are objectionable for the reason that they imply a pathological condition which has not been proved to exist. The term "Membranous Enteritis" employed by Da Costa is open to this criticism. Powell (1818) remarked that neither "the sort of pain nor the state of the pulse and skin seemed to indicate inflammatory action;" and this is true of the cases reported in this paper. Good (1822) called the malady "Diarrhœa Tubularis" giving prominence to indications, diarrhœa and tubes, which are only occasional attendants. Crampton and John Forbes¹ (1837), improving upon Good, termed it "flaky or membranaceous;" the result of a "peculiar inflammation," peculiar, certainly, if an inflammation. Whitehead's appellation of "Mucus Disease"—though less objectionable, perhaps, than those above mentioned—is also unsatisfactory; for while the chemical composition of the substance discharged may be similar to that of mucus, in its gross appearance and otherwise it frequently does not correspond with the latter.

To avoid theory and assumption where apparently there is so little knowledge, I have called it an *affection*, attaching a prefix to indicate a noticeable peculiarity which, if not strictly a membrane, is certainly, at first sight, *membrane-like*.

The ætiology of the disease is equally as uncertain as its pathology. Various authors have given their various solutions to this problem, all of which are open to many and serious objections. I will not venture to add any theory of my own.

The diagnosis can readily be established by a consideration of the clinical symptoms with an examination of the discharges. Such an investigation will eliminate intestinal worms, fragments of hydatids, intestinal diphtheria, dysentery, or the discharge of a portion of the bowel. Da Costa urges the importance of inquiring, in cases of anomalous nervous symptoms, particularly when happening in hysterical persons, where there is abdominal pain, into the possible existence of the malady under discussion.

The prognosis is rather unpromising for a complete recovery. Doubtless cases occur in which there is but a single attack of the disease with subsequent restora-

¹ Cyclopædia of Practical Medicine, American Reprint, vol. i. p. 634.

tion to health, but the rule, as the cases here reported show, is that there will be recurrences of the paroxysms with intervals of only partial freedom from discomfort and debility.

The treatment during the paroxysm, or when one is threatening, resolves itself into putting the patient in the condition most favorable to mitigate or endure the attending discomfort. Rest of body and mind, simple, easily-digested food, anodynes and sedatives, and such other adjuvants as may suggest themselves to the medical adviser, are to be recommended. During the intervals the endeavor should be to improve as far as possible the general condition of the patient. Many and varied, according to all authorities, have been the medicines employed to prevent the recurrence of the malady, but their results for the most part have been disappointing.

I have brought these cases to the notice of this Society in the hope that light may here be thrown upon a subject evidently obscure in itself, and still needing much elucidation so far as pathology and treatment are involved.

HOW THE COLOR-BLIND SEE COLORS.¹

BY PROFESSOR FRITHIOF HOLMGREN, UPSALA, SWEDEN.

MONOCULAR RED-BLINDNESS; MONOCULAR VIOLET-BLINDNESS.

THAT the color-blind do not see colors as the normal-eyed we may infer from the fact that they confound the kind of light which appears very dissimilar to the latter. When a red-blind can not distinguish the two sorts of light which the normal-eyed recognize as *red* and *green*, we can only conclude that the two look *alike* in color, but not that they appear of either one or the other color. We can at most say that they must appear of the one or other color, or of a third, such as we have in the system of the normal-eyed, yellow for instance, or of a color of which the normal-eyed has no conception. This is all we have a right to infer.

If a theory of color-blindness is to explain the connection of cause and effect, the first being the objective light and the second the subjective sensation of color, then this sensation must be understood. The various suppositions in favor of one or another of the several theories put forth on the subject have been naturally pressed forward. But till now there has been no solid ground of proof; we lacked facts and data. As, however, we have here to deal with subjective phenomena, the hope of obtaining such data had been given up, they were regarded as inaccessible to objective research.

Since we cannot control the subjective perception of another person, we cannot prove that all normal-eyed see colors alike. It may, however, be granted that, at least in reference to the principal colors, their quality is the same for all those who entirely agree in reference to them. There could not otherwise be any question of color between two individuals, just as there could be no intellectual agreement between man and man, if the functions of the senses were essentially different in the two.

Now, admitting this, and granting that all normal-eyed of themselves, and all the color-blind of the same class of themselves, see the principal colors essentially

in the same way, it may be shown that it is not only possible to decide how the color-blind see colors, but scientific and objective proofs can also be given.

There is evidently but one way to obtain a reply. Whilst preserving our own normal vision we must be put in the position to see at the same time with the eyes of the color-blind, and be able to compare their sensation of colors with the normal. But for this we cannot use either one or the other eye, if the two are not in organic living communication with the same brain. The normal-eyed must therefore become a part of the color-blind and exist in his senses whilst still preserving his own.

Such a double being is, however, a *conditio sine qua non* for us, but cannot be produced by grafting a normal-eyed on a color-blind, yet just such an organic combination of two different eyes with one and the same brain I shall now show is not only *not* an impossible thought, but even does exist in nature.

Color-blindness, as is known, is hereditary, and transmitted in accordance with certain laws.² One of these laws is that the defect does not touch all the children of the same parents, but spares some. Besides, it varies in degree in different individuals. It is not against, but rather in conformity with, the great law of heredity that an unequally transmitted defect should give us a person with one eye normal and the other color-blind, or one totally color-blind and the other incompletely so, or with a feeble chromatic sense, and therefore nearly normal.

Moreover, color-blindness may be acquired and so not necessarily affect both eyes at the same time. Hence it is quite possible to conceive of a normal and a color-blind eye connected with the same brain. Isolated cases of this have been reported, one quite recently by O. Becker, of Heidelberg.³ Here we have the double person sought for, in whom the color-blind part can describe his subjective color-sense to the normal-eyed part, and *he* can make it objectively clear to other normal-eyed persons. Here is the bridge between the subjective sensation of the color-blind and the objective investigation of science.

Thus guided, I have carefully searched, in connection with the extended statistical examinations for color-blindness in various directions in Sweden, for a case where one eye only was defective. The difficulties which one always meets with in detecting color-blindness, and which my worsted method first removed to any extent, were for certain reasons more prominent here than usual. I have heard here in Sweden of but one case (in the summer of 1879), which most unfortunately an accident rendered useless for my purposes.

Having succeeded in a practical method of assisting the detection of such cases, I had, within a comparatively short time (June to October, 1880), opportunity of examining not less than two, the first being one of monocular violet-blindness, and the second, for which I have to thank Professor Hippel, in Giessen, a case of monocular red-blindness.

Experience points toward such cases not being so rare as heretofore thought, and hence a complete solution of the question at issue may be thus reached by the method I have entered upon. The plan, principle, and result of the investigations are in brief as follows:—

First of all the color sense of each eye was deter-

² Vide translation of the case in this journal, May 6, 1880.

¹ Centralblatt für med. Wissenschaften, Nos. 49-50, 1880. Translated for the JOURNAL by Dr. B. Joy Jeffries.

mined separately. In both the cases tested there was complete typical color-blindness in one eye (in the left of the violet-blind, and in the right of the red-blind), and in the other eye a feeble color-sense, but so slight, so near normal, that the person could distinguish readily all the principal colors, only failing in the very palest and the very darkest. The cases were, therefore, perfectly adapted for my purposes. The principle governing all the details of the examination was that of comparison. I let the normal eye compare the sensations of the color-blind one with its own, and put the result thus obtained in a form to be readily appreciated by all normal-eyed.

A person with monocular color-blindness has, of course, with his other eye the same idea of colors as the normal-eyed, and can express to the latter just how colors appear to his color-blind eye. We may, therefore, trust his color names as we cannot those of the person with both eyes color-blind.

Here, however, as usual, words are less important than acts,¹ and as description is always less accurate than an objective representation and demonstration, I have always let the person show by colors chosen with the normal eye the sensation his color-blind eye receives. We thus also find indirectly what sensations are wanting in the color-blind eye compared with the normal-eyed. Direct evidence of this we obtain by the reverse, namely, when we let the color-blind eye control the subjective color sensations of the normal eye. The details of the carrying out this principle I reserve for a future more extended publication, both in reference to methods and the results obtained.

To indicate here briefly the principal data can be best done by a simple description of the subjective spectrum of the color-blind. Starting with the solar spectrum, and the subjective spectrum of the normal-eyed as a basis in describing the several kinds of light, we have the following:—

It has been assumed on good ground that the color-blind see only two principal colors in the spectrum. These are the two fundamental colors of his subjective color system. In the violet-blind's spectrum the fundamental colors are *red* and *green*. His spectrum is not shortened at the red end. From the red end his first fundamental color reaches through the red, orange, and yellow of the normal-eyed. First at yellowish green (just beyond the Fraunhofer line D) he sees a neutral colorless small band, beyond which the second fundamental color green commences, becoming more saturated, and then darker over the green, greenish blue, cyan blue, and indigo blue of the normal eye up to violet, where his spectrum wholly fails (about the line G). The violet-blind's confusion with colored pigments is thus explainable (green with blue, purple and red, orange and yellow, violet with yellow, green, and gray).

Now this will all be found to be in complete harmony with the Young-Helmholtz theory. As to the tone of the fundamental colors of the violet-blind, his red is not quite identical with the spectral red of the normal-eyed (cinnabar), but a purer red (more like carmine), nearer to the extreme red as seen by the normal-eyed. The other base color of the violet-blind is green, a pure green, having to the normal eye a slight tinge of blue.

The two base colors of the red-blind are *yellow* and *blue*. Their yellow begins further on than with the red of the normal-eyed (about the line C), reckoning from the red end, and reaches over the rest of red, orange, yellow, and green, ending in bluish green (between the lines b. and F), nearer the latter, where a neutral, colorless small band forms the border to the second base color *blue*, which spreads from here on over the cyan blue, indigo, and violet as seen by the normal-eyed. His spectrum is not shortened at the violet end. The mistakes the red-blind makes with pigments are hence readily explainable (confusing green and yellow, orange and red, purple and blue and violet, extreme red with greenish blue and gray).

This, therefore, agrees objectively with the Young-Helmholtz theory. Subjectively considered we should have, perhaps, expected green to be the first primary instead of yellow. I long ago explained² that yellow and not green is the first primary of the red-blind, and, as did Fick,³ later, that this did not conflict with the principles of the Young-Helmholtz theory. The tone of the first subjective primary color of the red-blind, so far as could be in this case determined, was not pure gold yellow, but a yellow that to the normal eye had a tinge of green in it, in brighter nuances, more like lemon yellow, and in darker nuances more olive green. The red-blind's second color is not a pure cyan blue or indigo, but more of an indigo violet.

Full understanding of the theory in this respect can only be had through opportunity of testing several cases of monocular color-blindness of the several kinds and of different degrees, and, first of all, a typical case of complete green-blindness. We may, however, now consider the road open by this method for answering the theoretical problem of color-blindness, which I shall explain in detail in a future more extended publication.

RECENT PROGRESS IN PHYSIOLOGY.

BY G. M. GARLAND, M. D.

HEAT OF BODY.

WE recently took occasion to commend Dr. Wood's memoir⁴ as a model of skillful physiological investigation, and further study of it only intensifies our admiration of its merits, and we offer the following imperfect summary of its leading points.

The chief phenomena of fever are capable of being grouped into four sets: acceleration of the heart's beat and disturbance of the circulation; nervous derangement; disturbance of nutrition, including secretion; elevation of bodily temperature. Of these four conditions the only one which seems absolutely essential, and capable of producing the others, is elevation of the bodily temperature, and therefore Wood assumes this to be the characteristic feature of fever. By a series of experiments he shows that artificial heating of the body in an oven will produce disturbances of circulation and innervation similar to those present in ordinary fever. Heating of the brain by a hot-water bonnet, or by the sun, will cause symptoms of fever, even convulsions and death. Prolonged artificial heat

and continued fever also cause similar nutritive changes in the liver, heart, kidneys, and muscles. It appears, therefore, that elevated bodily temperature is not only a constant feature of fever, but it is capable of producing, *de novo*, all the other phenomena specified, and therefore Wood considers that the aphorism of Galen, "*Nam essentia quidem februm est in caloris præternaturem*," is firmly and logically grounded.

The next question which naturally presents itself is in regard to the mechanism by which the production and dissipation of heat are regulated in the animal organism, and the second chapter of the memoir is devoted to the investigation of this point. An attack was made upon the nervous system by a series of sections of the spinal cord at different levels. Cutting the cord in the lower cervical region caused the bodily temperature to fall rapidly, and it remained permanently low until death occurred, provided the temperature of the air surrounding the animal was lower than his own. If the animal, after section, was placed in a hot atmosphere, or was protected by a cotton pack, the primary fall was soon replaced by a rise, and the animal died with his temperature above normal. Careful calorimetric estimations showed that the fall of temperature was mainly due to an increased dissipation of heat, and that this increase was caused by a dilatation of the peripheral capillaries from vaso-motor paralysis, but it was still a question whether this increased dissipation was associated with increased production of heat. It is evident that there must be an increase of production if the increased dissipation remains permanent, because excessive elimination would soon exhaust the reserve heat of the body, and it could then still continue in excess only by increase of supply. Further investigation revealed that the primary increase was not maintained. And yet there was an evident rise of temperature when the body of the animal was protected from external cold. Wood concludes that section of the cord in the cervical region produces a vaso-motor paralysis and an increased loss of heat. The resulting lowering of the bodily temperature caused a diminished production of heat by checking chemical processes. Where this lowering of bodily temperature is avoided by external warmth there seems to be an increased production of internal heat. The author next desired to further simplify the problem by removing the disturbing influence of the vaso-motor nerves. Of course it is impossible to isolate the vaso-motor fibres in the cord itself, but research has shown that the vaso-motor centre from which these nerves arise is situated in the medulla in the floor of the fourth ventricle. Section below this point produces vaso-motor paralysis, while section above the same will leave the peripheral circulation undisturbed. Pursuing this physiological indication, Wood found that section of the medulla below the vaso-motor centre produced results similar to those which follow the cutting lower down. Section above the point mentioned, that is, between the medulla and pons, causes an immediate rise of bodily temperature. The amount of heat dissipation is somewhat increased, but the heat production becomes so much greater that a rise of temperature results.

Various explanations have been advanced to account for this rise of temperature after section between pons and medulla. One set of observers think it is due to irritation of vaso-motor centres, that is, to a spasm of the peripheral capillaries. Wood argues strongly

against this theory, and thinks that section of a nerve means paralysis, not irritation. He believes there is a centre situated in or above the pons, whose function it is to exert a restraining influence upon the nutritive processes in the various tissues of the body: that is, it is an inhibitory centre. Section between the pons and medulla destroys the function of this centre: thereby removes the governor, and hence the rise. Elevation of bodily temperature, therefore, according to Wood, is probably due to paralysis of an inhibitory heat centre.

It has been pretty clearly established that the thermometer is no measurer of the amount of heat generated in a body, but merely indicates the amount held in reserve at any one time. This reserve amount, moreover, is determined by the play between the functions of heat production and heat dissipation, and hence an elevation of the bodily temperature does not necessarily mean an increase of the chemical movements of the tissues, nor does a low temperature militate against an increased heat production. A dog which is perfectly well and has been fed high will produce more heat units than a dog which is suffering from pyæmia. Yet the fed dog's temperature will be normal, because his heat elimination is equal to the heat production, while the pyæmic dog's temperature is elevated.

The following table of Professor Sanderson shows these peculiarities of heat production in human beings under different conditions:—

Heat production in fever, on fever diet,	2021 K. units.
Heat production in health, on adequate diet,	2118 K. units.
Heat production by excessive diet may reach	2700 K. units.

Here it is observed that the amount of heat produced in fever may be less than that produced on ordinary diet, though usually the production of animal heat rises in the febrile state with the temperature and with the stage of fever. In order to understand these points it is necessary to remember that there are two distinct sources of heat in the body, namely, the food which is floating in the blood, and the stored-up material of the various tissues. If the food be excessive then the amount of heat generated becomes increased. If the food be inadequate then the stored-up material suffers. In fever there appears to be an increased tissue metamorphosis combined with inadequate food, so that Wood defines fever as "a complex nutritive disturbance in which there is an excessive production of *such portion of the animal heat as is derived from chemical movements in the accumulated material of the organism*, the overplus being sometimes less, sometimes more, than the loss of heat production resulting from abstinence from food."

With regard to the origin of fever, Wood is a strong advocate of the neurotic theory, although allowing that many fevers are due to some poison circulating in the blood, and that they may be termed hæmic fevers, in so far as they are induced by the injection of such material into the blood, for he thinks the tissue changes which characterize fever are produced, not by the local action of the poison, but by the mediate influence of nerve centres, which in their turn are deranged by the poison. Fever is "simply a state in which a depressing poison or a depressing peripheral irritation acts upon the nervous system which regulates the production and dissipation of animal heat. . . . The so-called inhibitory nervous system is not paralyzed in fever, but is less capable than in health of answering promptly and powerfully to suitable stim-

uli; in other words, it is in a condition of paresis or partial palsy. . . . In fever vaso-motor paralysis which produced is followed by an immediate fall of temperature similar to but greater than that which is produced by a like disturbance in health."

Thus we have endeavored, with imperfect success, to point out some of the leading topics which are treated so thoroughly and scientifically in this book. We heartily advise those who are at all interested in this subject to read the memoir itself, and we assure them that they will find the subject presented in a very fascinating manner.

ERUCTATIONS.

Foster¹ says, "In the act of swallowing no inconsiderable quantity of air is carried down into the stomach, entangled in the saliva or in the food. This is returned in eructations. . . . The enormous quantity of gas which is discharged through the mouth in cases of hysterical flatulency, even on a perfectly empty stomach, . . . presents difficulties in the way of explanation; it is possible that it may be simply diffused from the blood." Nearly all other writers who speak of this subject define eructation in a similar way by saying that it is the sonorous emission of flatus from the stomach through the mouth. Dr. Weissgerber² has recently published some investigations on this point, which are very interesting. He had under observation, in the medical clinic at Giessen, a man who was endowed with the power of eructation to a remarkable degree. Like the croaking frog of Goltz, it was only necessary to stroke his abdomen, or to touch any part of his body, in fact, to elicit a belching explosion from the mouth. He looked in perfect health, but his wife thought he had hysteria.

Struck by the apparently inexhaustible supply of gas which the patient had at command, Weissgerber tried to imitate in his own person the movements which the patient made in producing the explosions, and after several days' trial he found that he could likewise produce any number of eructations at will. As the result of his experiments he concludes that eructations should be properly divided into two classes, namely:—

(1.) Natural eructations, or those in which gas escapes from the stomach, and is impregnated with the odors of the food ingested.

(2.) Artificial eructations, or those in which air is drawn into the œsophagus and reëxpelled without entering the stomach.

The œsophagus forms a tubular bag, which is closed below by the constriction of the cardiac orifice, and above by the pressure of the larynx. In order for air to get in or out of either end of the œsophagus, therefore, a certain amount of force is necessary to overcome the resistances mentioned. This is accomplished in natural eructations by the following agencies:—

I. Gas may be expelled from the stomach by simple contraction of that organ during quiet respiration.

II. Gas may be pressed out of stomach and remain in œsophagus until the pressure of the next expiratory contraction of the chest expels it.

III. The muscles of stomach and abdominal walls may act in concert.

IV. Air may be sucked up into the œsophagus from the stomach by the negative pressure which is produced in the œsophagus during the inspiratory enlarge-

ment of the chest. Subsequently, the same gas is expelled by the succeeding expiratory contraction of chest.

The artificial eructations are very different from the above, and after a little practice may be called forth at will at any time, in any strength, and with any desired rapidity. They are produced by the alternate admission of air into, and the expulsion of the same out of, the œsophagus, and consist of two easily distinguishable sounds. The first sound is produced by the air as it is forced into the œsophagus, either by the negative inspiratory force of the chest or by the act of swallowing. Weissgerber says that during this act a strong inspiratory effort is made; the larynx is elevated and the glottis is closed. He affirms that he could never swallow air or force it into his stomach without first filling the œsophagus by an inspiratory effort. We have tested these points on our own throat, however, and find that it is possible to swallow air without an inspiratory suction, and we can feel the air trickle into the stomach after an interval of a few moments, provided we refrain from expelling it upward. Moreover, with the inspiratory method it is not essential for the glottis to be closed, because we can hear air enter the trachea and œsophagus simultaneously.

Sometimes the first sound may be absent, and in those cases Wood thinks that the air is drawn very gently past the larynx without producing any sound.

The mechanism of the second sound is less difficult to understand. It is simply an explosive escape of the air, which is squeezed out of the œsophagus by an increased intra-thoracic pressure. During this stage the glottis is firmly closed, and it is apt to open with a little explosion of its own immediately after the eructation is completed.

In this connection it is interesting to recall an observation made many years ago by Professor Freund in a little treatise upon the relation between pulmonary diseases and primary anomalies of the costal cartilages. He says that the suddenly recurring tympany of hypochondriacs and hysterical persons can scarcely be referred to other causes than to a suddenly-occurring and transient paralysis of the abdominal muscles. The complete odorlessness of the air belched out shows that it is not developed in the bowels. The mechanism of this phenomenon is simple. The relaxed abdominal wall sinks downward and forward by its own weight and that of the inclosed organs. The vacuum thus created in the stomach and intestine is filled by air which enters from the mouth. He adds that one may readily observe people also *swallowing* air involuntarily. This he terms an abdominal inspiration, which, unlike thoracic inspiration, is of a passive (paralytic) nature.

This explanation by Freund of the rapid inflation of the stomach, which is so often seen in hysterical subjects and in those persons who are slightly nauseated by any cause, seems hardly satisfactory, and we think the condition is better explained by the suggestions of Weissgerber.

IODOFORM.

Dr. Peterson claims that the odor of iodoform can be completely masked by the addition of tincture of must in the proportion of one drop to the ounce of iodoform whether in the solid or fluid form. — *Peterb. Med. Woch.*

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

MAY 23, 1881. DR. T. B. CURTIS presided.

DR. H. I. BOWDITCH presented the portrait of Dr. J. B. S. Jackson into the care of Dr. Holmes, with the following words:—

GENTLEMEN OF THE BOSTON MEDICAL LIBRARY ASSOCIATION AND OF THE SOCIETY FOR MEDICAL IMPROVEMENT.—We meet together this evening to make a formal agreement with one another for the future careful preservation of the portrait of one of our most distinguished and respected associates, now no longer living.—Dr. John B. Jackson, of this city.

DR. HOLMES.—It gives the members of the Medical Improvement Society great pleasure to put into your hands, as president of the Medical Library Association, the portrait which is before you. We beg of you to take charge of it, and to direct that it shall be forever kept with care, and in the sight of all who may visit the library. It will probably remain always with you, but the society, while placing it under your care, does not wish to relinquish the legal ownership thereof.

We feel sure that you will never possess the portrait of a nobler example than he was to the medical profession. We rejoice to feel that by it you will transmit to physicians yet unborn the perfect likeness of one who commanded the respect and esteem of us, his contemporaries, alike for the purity of his character and life and for his unbounded zeal for our honorable profession.

Written upon the back of the portrait are the following words:—

"Sancte inziolate que servatum sit."

I cannot close these few remarks better than by heartily commending them to you and your associates and successors as containing the proper spirit in which the portrait ought to be guarded by all of us and by our descendants.

DR. HOLMES received the portrait, and addressed the Society.¹

DR. CURTIS tendered the thanks of the Society to Dr. Holmes.

DR. GOSS read a paper entitled

A MEMBRANE-LIKE AFFECTION OF THE BOWELS.

Vide page 507.

DR. CUTLER said that he had nothing to add to the description of the affection which had been so well given by Dr. Goss. He had seen a number of specimens of the so-called membrane, some rope-like and tough, as in a sample recently sent him by Dr. Lyman; others long and tubular, notably one procured from a patient of Dr. Cowles a few years ago. They all consisted of tough mucus. He had never seen anything like these collections of inspissated mucus at autopsy, although mucus similar to that discharged in dysentery was not rarely met with. Woodward, in the *Medical and Surgical History of the War of the Rebellion*, Medical Volume, second part, page 363, gives, perhaps, the most complete bibliography of the subject. The

¹ The Address of Dr. Holmes will be printed in the JOURNAL of June 9th.

idea that the trouble was of bacteritic origin had been entertained by at least two writers, but as no other careful observers speak of the rod-like organisms they found, or, indeed, of any others, it is fair to assume that their presence in the instances mentioned was merely accidental. A very great proportion of the patients were women, as Dr. Goss had said, and were either hysterical, hypochondriacal, or suffered from nervous or gastro-intestinal disturbances.

DR. BOARDMAN said that he had met with three or four cases, and they all occurred in hysterical women. He mentioned the case of a lady who thought that she had a tape-worm, who at times passed a pint of this membranous material. She continued to pass this for a year, when the rubber-like masses changed to a sago-like consistency, and now at times, whenever she is hysterical, she has what she calls hæmorrhages, but which are mostly liquid mixed with a little blood. There seems to be a gradual improvement; her only troubles have been hysteria and constipation.

DR. C. P. PUTNAM asked if it was possible to draw the line between these cases and a certain kind of constipation arising from want of activity of the intestines, where the mucous membrane was kept in a condition of slight irritation a large part of the time, yet not often actually inflamed. Fæces may, as is well known, lie in the intestine a long time, and may then either cause no perceptible irritation, or give rise to occasional diarrhœa; but also in a condition between these two, the faecal masses may cause the formation of large masses of mucus, which do not show themselves unless there is an unusually free movement of the bowels, but usually get pressed into the tubes and ribbons described. It was not surprising that hysterical women should be so affected, as they are the very ones where the required conditions—inactivity and insensibility of the bowels—are frequently found. As a rule such patients have learned, as they think, to regulate their bowels, and manage to get a movement every few days, while in fact they leave a part of the fæces lying in the intestine all the time. In such cases frequent large injections of hot water (a quart or more) produced a great change in the condition of the contents of the colon.

DR. FITZ remarked that during the last ten years he had frequently had specimens sent him for examination, and that the history was almost always that they were hysterical and constipated women.

The specimens suggested the large intestine as their origin, and he thought that constipation might very well be the cause of the trouble.

DR. BOWDITCH asked whether it was not uncommon to find these appearances at autopsies, for otherwise it would rather point to something different for irritation from constipation.

DR. FITZ had not found any appearances of this kind in the autopsies which he had made.

DR. BOARDMAN thought if it was not something different it would have been met with, for many people die when in a state of constipation.

FALSE ANCHYLOSIS OF HIP-JOINT.

DR. BRADFORD exhibited for Dr. Buckminster Brown an apparatus for treating the hip-joint, and read Dr. Brown's remarks on this subject:—

An efficient apparatus for the treatment of contraction and false anchylosis of the hip-joint has long been a desideratum in orthopaedic surgery.

In former times these sequelæ of morbus coxarius were more frequently met with than now, when the acute stages of the disease are more scientifically treated. Still, cases in which the femur is fixed at angles, varying from an acute or right angle to one where the foot is but slightly raised from the ground, are not of uncommon occurrence.

For twenty-five or more years it has been my practice to operate upon contracted muscles, tendons, or cicatricial tissues connected with the knee or hip joints: first, by subcutaneous section in the hip of the adductor longus, tensor vaginæ femoris, rectus, or sartorius, and in the knee of the biceps flexor cruris, semi-tendinosus and semi-membranosus, or such of these tissues as required division; followed by forcible rupture of the more deeply-seated adventitious impediments to free movements, — this *brisement forcé* being in all cases carefully gauged and measured as to the degree of power employed by the amount, estimated under ether, of resistance to be overcome.

After the joint has been thus loosened, and partially or completely straightened, the treatment in the knee is facilitated by the firm bearings to be obtained on the femur above and on the bones of the leg below. In the hip it is otherwise. The pelvis does not afford a fixed basis from which to act on the femur.

The best instruments in use by European and American surgeons but partially fulfill the required indications.

The attempt to extend the femur with any of these instruments causes the universally-recognized tilting of the pelvis, producing lordosis to a greater or less extent, thus more or less neutralizing the action of the apparatus.

The application commonly used, namely, a steel pelvic belt, with a long spring extending behind the trochanter and femur to a short distance above the knee, and strapped to the femur near its extremity, is inefficient and unreliable. It becomes easily shifted from its proper position, and when in position is rendered almost powerless by causing the incurvation of the lumbar vertebræ.

This instrument I modified by adding a broad back-board of steel, attached by a broad basis to the pelvic belt, and extending to the middle of the scapulæ. To this back-board, embracing its entire length from scapulæ to pelvis, was attached a wide abdominal belt. By this addition an endeavor was made to antagonize the action of the spring on the femur.

The desired result was not fully attained by this contrivance.

The inefficacy of the weight and pulley in cases of the nature under consideration needs no demonstration to any one who has tried the experiment.

It is requisite, in the first place, to render the pelvis a fixed centre, firm and immovable, — so firm that the leverage on the femur shall not raise the posterior brim and produce incurvation of the spine by the action of the unsevered contracted muscles and ligaments connected with the pelvic bones, and by the antagonism of the muscles arising immediately from the lumbar vertebræ and ilium.

Secondly, to secure an instrument by which, using the femur as a lever, we could extend or flex, abduct or adduct, from the joint.

These movements, to be effectual, must be carefully graduated and guarded to avoid pain, yet steady and *sure* in their action. To overcome these obstacles and

to meet these requirements constituted the problem to be solved.

Professor Bauer, in his Orthopædic Surgery, when treating of fixation of the hip, describes and pictures a concave block of wood, which is accurately turned and adapted to the posterior pelvis and nates from a plaster mould. This block, with the required straps, serves as a counter-extension to the weight and pulley, by which he makes direct extension.

The mattress arranged for the patient is divided into two unequal parts, and the block is placed between them: the shorter portion for the head and shoulders, and the longer for the lower limbs.

The apparatus now presented to the society consists of such a concave block, into which the pelvis sinks. The box is so shaped as to raise the lower part of the sacrum. The nates fit into cavities moulded for them, and the thighs lie in two troughs separated by a prominence rising up towards the pubis. A strong, wide, heavily-padded leather strap is fastened to the box on each side, and buckled anteriorly over the ilii, thoroughly securing them in position. From each side of the block, extending on the sides of the chest towards the axillæ, are two steel rods with knobs. To these rods is attached a belt of thick webbing, eight or more inches wide, which is strapped over the abdomen, and assists in preventing any rising of the lumbar vertebræ.

By these means the pelvis is rendered a solid fixture. To the upper edge of the box or block, and parallel with the anterior margin of the ilium on each side, a narrow bar of steel is screwed, which extends on a level to the lower third of the femur, just above the knee.

At this extremity of the bar are notches which admit the thumb-screw of a padded steel band which grasps the femur. This band is movable to allow of change of position and pressure, and swivels on a pivot to adapt itself to any angle required. In this bar or rod, opposite the hip-joint, two ratchet-screws are inserted, one moving the free extremity of the rod upward and downward, the other acting laterally inward and outward. The pelvis being first secured, as before described, we have here an almost irresistible force with which to extend or flex, abduct or adduct, and this may be accomplished by movements so regulated and graduated as to be almost imperceptible to the patient.

Practically, this has proved the only efficient apparatus for straightening the hip in the difficult cases to which I have referred. All who have attempted to treat cases of this description must have experienced the need of such an instrument.

NOTE. The block is so divided that a section can be removed to give place to a galvanized iron pan for the reception of the alvine and vesicle discharges.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

EMMET'S OPERATION FOR LACERATION OF THE CERVIX UTERI.

At the last meeting of the County Medical Society, May 23d, Dr. C. C. Lee, one of the surgeons to the Woman's Hospital, read a paper on The Proper Limitation of Emmet's Operation for laceration of the

Cervix Uteri. Among the contra-indications for the operation he mentioned pelvic cellulitis and peritonitis, as well as endometritis and acute cervicitis in the great majority of instances. There were also various general conditions which contra-indicated it, such as very marked anemia, chlorosis, constitutional syphilis accompanied by vaginal lesions, carcinoma, and, in short, any unfavorable state of the system, unless, indeed, the latter were due to the laceration. In selecting cases for operation the cardinal point was to be guided strictly by the *pathological import* of the laceration, and not by its extent or special character. In the course of the paper Dr. Lee alluded with approval to the practice originated by Dr. M. A. Pallen of operating upon the cervix immediately after labor in cases of post-partum hemorrhage due to laceration of the latter.

In the discussion which followed the reading of the paper, Dr. Emmet said that, in the light of his present experience, he would confine the scope of the operation within even narrower limits than Dr. Lee. The mere existence of a laceration of the cervix was of no special significance, and if there were no evil effects resulting from it there was not the slightest necessity for resorting to operative interference. When pelvic cellulitis was present in connection with laceration of the cervix, it was the physician's duty to cure the cellulitis first; and it would be found in a large proportion of cases that after this was accomplished all the patient's trouble disappeared, and no operation at all was required. This good result he believed to be due to the beneficial effect upon the circulation of the cervix of the removal of the pelvic inflammation, which always interfered seriously with the latter. If, however, the gap in the cervix were filled with a plug of cicatricial tissue, and the patient were anemic and affected with reflex symptoms, such as the various forms of neuralgia in different parts of the system, the operation was strongly indicated, and the most happy results might be expected to follow it.

Dr. Emmet was followed by Dr. Pallen, who contended, on the other hand, that the scope of the operation should rather be enlarged than further curtailed; believing that if it were performed more frequently, and in cases where there was at the time no trouble apparent, it would be the means of preventing mischief that would be very likely to ensue in the future. Among the other speakers was Dr. Polk, professor of obstetrics in the University Medical School, who expressed the opinion that in ordinary labors a great many lacerations of the cervix occurred which might otherwise be avoided, as a result of the premature rupture of the membranes by the accoucheur; and, in bringing the discussion to a close, Dr. Lee suggested that, in addition to the cause of laceration mentioned by Dr. Polk, the accident not infrequently resulted from the practice of dilating, or attempting to dilate, the cervix by means of the fingers.

—Subscribers wishing to pay their subscription for the Boston Medical and Surgical Journal will find an agent at the coming meeting of the Massachusetts Medical Society at Horticultural Hall, Boston, June 8th.

—A training school for nurses has been started in connection with the Mount Sinai Hospital, a building having been secured for the residence of the pupils, and a graduate of the Bellevue school placed in charge.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.¹

SECOND DAY. GENERAL SESSION.

DR. HUNTER MCGUIRE, of Richmond, chairman of the Section on Surgery, delivered a suggestive address upon Operative Interference in Gunshot Wounds of the Peritoneum, in which he took advanced ground in favor of interference as opposed to the expectant treatment.

Statistics from the Crimean, the French, and the late civil war in America show that more than nine out of every ten cases of wounds of the belly, opening into the cavity of the peritoneum, perish,—no other gunshot wounds being so deadly, not even penetrating and perforating wounds of the skull. In incised, punctured, and gunshot wounds of the peritoneum, the general plan of treatment has been to enjoin absolute rest, give opium to prevent peristaltic action, and encourage the formation of adhesions, in the idle hope of preventing extravasation into the peritoneal cavity.

In the opinion of the writer, when we remember that the alimentary canal is never completely empty, common sense teaches us, when an opening is made in any portion of the peritoneal cavity, that its contents will escape; that there will probably be less resistance to the passage of fecal matter through the unnatural aperture than along the sides of the canal itself. Gas may first be expelled, separating peritoneal surfaces, and then the fluid or solid contents of the bowel follow. Only one or two exceptions to this rule are reported in the history of the late war between the North and South. But, besides alimentary effusion, blood, air, bile, and urine may also be extravasated into the peritoneal cavity. Penetrating wounds of the belly, with fecal effusion, are rapidly followed by general acute peritonitis; ninety per cent. die, and within forty-eight hours. Does peritonitis from any other cause, as a rule, kill as quickly? In spite of the assertion of Malgaigne and others, that the organs contained in the belly fill the cavity to such repletion that shot wounds of that space without visceral injury are impossible, post-mortem examinations and experiments upon dead bodies show that wounds of the peritoneum can be made without injury to the contained viscera. It has fallen to the lot of the writer to witness four such cases. Two occurring in civil life, and being the subjects of legal investigation, careful autopsies were made. Two were soldiers dying from peritonitis, and the autopsies showed no visceral lesion. These four cases coming under the observation of one individual, and having their exact character shown by post-mortem examinations, prove that such results are not impossible, and probably not as rare as we have been led to suppose. Those rare cases of recovery from penetrating wounds of the abdomen have induced surgeons to continue the expectant plan of treatment in place of what appears, at first sight, to be a desperate surgical interference. Some of the alleged recoveries may have been wounds of a portion of the large intestine not covered by peritoneum. Recovery, with fecal fistula, is not uncommon in this case. Others may have been penetrating wounds without visceral injury; others, again, may have been parietal wounds without peritoneal penetration. In connection with the four cases of gunshot wounds of the peritoneum alluded to by the writer, and in which there was no visceral in-

¹ Concluded from page 474. Our reporter wishes to acknowledge his indebtedness to the Virginia Medical Monthly.

jury, the total absence of shock was remarkable, and no diminution of temperature was present. One of them (a soldier) assured the writer that he did not know that he had been wounded until some time after he had been shot. Another (wounded in a duel) insisted that he was able to stand up and fire at his antagonist again. On the other hand, in all cases with visceral lesions the shock of injury is a prominent symptom. The presence or absence of shock seems to be a diagnostic point of no little value. If to this be added sudden meteorism, the character, extent, and direction of the wound, bloody discharges from the bowels or stomach, an almost certain diagnosis by rational symptoms will be reached. In reply to the question, Why are these injuries so fatal? the writer attributes death to some kind of blood-poisoning connected with peritonitis, just as we often see septicæmia associated with peritonitis under other circumstances, notably after parturition and ovariectomy. Dr. McGuire believes that the blood-poisoning after gun-shot wounds of the peritonæum is consequent upon the pent-up, sero-fibrinous exudation which traumatic peritonitis invariably produces in abundance, and that if this effusion could be drained off as soon as it is formed septicæmia might be prevented. In lacerated wounds of the abdominal walls, with exposure of the cavity, protrusion of the contents and the introduction of foreign matter into the cavity are nothing like so mortal.

In all of these cases the nature of the wound prevents union by the first intention, and drainage of abdominal effusions is effected. In the fifty-nine cases of recovery after penetrating wounds of the large intestine fifty-five were perforating wounds, the large aperture of exit being usually on the posterior surface of the body, dependent, and facilitating drainage. In one of the four instances of recovery in simple penetrating shot wound of the large bowel, the edges of the opening in the bowel were fastened to the wound in the abdominal wall, and in this, as well as in the other three cases, fecal fistulae were formed. Shot wounds of the pelvis are nothing like so fatal as wounds of the peritonæum higher up. Unless accompanied by grave visceral lesion, three cases out of four of penetrating or perforating wounds of the pelvis recover. Can this fact be satisfactorily explained upon any other theory than that drainage in these wounds is almost unavoidable? Indeed, in these cases we are taught to explore the wounds with the finger, remove loose pieces of bone and foreign bodies, and keep the aperture of entrance and exit open, that free vent may be given to all inflammatory products; and if the size and position of the wound do not facilitate this we make the opening bigger and insert a drainage tube. Spencer Wells attributes the fatality after ovariectomy to some form of pyæmic fever, or some form of blood-poisoning so often associated with peritonitis, and thinks the lesson taught by many successful ovariectomists of providing for the escape of inflammatory matter of great value, and one which should be recalled by the surgeon who treats gun-shot wounds of the peritonæum. Ovariectomists even go so far as to wash out the cavity when peritonitis exists and death from septicæmia is imminent. In many of the cases of penetrating wounds of the peritonæum the ball passes obliquely through the abdominal wall, and the aperture shuts up like a valve, or, if passing directly through the parietes, the aperture of entrance contracts at once and closes. To all intents and purposes the cavity is

hermetically sealed, and the missile, pieces of clothing, blood from wounded vessels, fecal effusion, if the intestine is wounded, and inflammatory products, are all hopelessly imprisoned there. Can it be wondered at that such wounds are fatal? In no other gun-shot wounds of cavities do we allow the wound of entrance and exit to be closed. Who would think of shutting up the opening in gun-shot wound of the knee-joint? During the late war the plan of hermetically sealing up wounds of the pleura, a structure analogous to the peritonæum, proved most disastrous. In gun-shot wounds of the chest, involving the serous membrane, we keep the wound patent, and, if not dependent, we do not hesitate, when effusion takes place, to make a counter-opening with a knife or trocar, and sometimes to flush out the cavity with detergent and antiseptic lotions. In view of these facts the writer ventures to advocate operative interference in gun-shot penetrating wounds of the peritonæum, with intestinal injury, in penetrating wounds of the peritonæum with any visceral lesion, and in similar cases without visceral injury. The wounds in the abdominal walls should be enlarged, or the linea alba opened freely enough to allow a thorough inspection of the injured parts. Hemorrhage should be arrested. If intestinal wounds exist, they should be closed with animal ligatures, trimming their edges first if they are lacerated and ragged. Blood and all other extraneous matter should be carefully removed, and then provision made for drainage. If the wound of entrance is dependent, drainage may be secured by keeping this open. If the wound is a perforating one, and the aperture of exit dependent, the patency of this should be maintained, and, if necessary, a drainage tube of glass or other material introduced; if there is no wound of exit, and the wound of entrance is not dependent, then a dependent counter-opening should be made and kept open with a drainage tube. If it is urged that the means suggested are desperate, it can be said in reply that the evil is desperate enough to justify the means.

Dr. J. S. Billings, U. S. A., read a paper prepared for the Section on State Medicine, on Some of the Results of the Tenth Census as regards Mortality Statistics.

Early in the census year forms were prepared for a small register of deaths to be kept by physicians.

Each register contained twenty-four such slips, and a copy of the register, with a stamped envelope for its return at the end of the census year, was sent to every one in the United States who was reported by his or her postmaster to be a physician or to be addressed as such.

The registers, having been received, were examined by a skilled physician, who indicated on each slip the name of the cause of death to be used in tabulation. Very few of the registers were in such a condition that they could not be used for statistical purposes, although, as a matter of course, some of the causes of death reported could only be classified as unknown. This had been foreseen, and in the address above referred to it was expressly provided that the physician should use such terms as "paralysis of heart," "apnoea," etc., as equivalent to "unknown."

This point was not, however, made quite so clear as it should have been in the registers, as will be seen by examining the foot-note of instructions, although the intent was probably understood by the great majority of physicians. The number classified as "unknown"

was 4162 out of a total of 166,896, being about 25 per 1000.

The number of post mortems made in this number of deaths was 3755, or 20.7 per 1000.

When the examination and checking of these registers was completed they were taken apart, and as each leaf furnished the record of a single case they could then be used as cards, and readily assorted and classified in various ways. The first classification was into groups by counties. Those coming from the large cities were then set aside, and the remainder, representing the character of the fatal diseases in rural districts and small towns, were so compiled as to show by age, sex, and color the number of deaths from each cause.

The unit of area or locality used in this compilation was neither the State nor the county, but groups of counties in each State, selected according to altitude and topographical characteristics by the geographer of the census. Each State contained from two to six such groups, and thus we can group the prevailing causes of death on the sea-coast, on the table-lands, among the hills, etc.

As the number of deaths returned by physicians upon these registers has no definite relation to the actual number of deaths which occurred in any given locality, and still less to the actual population of that locality, these registers can only be used in this connection to show the proportional frequency of certain causes or groups of causes of death to the whole number of deaths reported in them or to each other. They have other and important uses.

The nomenclature and nosological classification adopted are essentially those used in the last census, being that prepared by the Royal College of Physicians.

The most important differences in it from the old nomenclature of the college are the abolition of the division of general diseases into two groups, — A and B, — and the placing in the general diseases the various forms of diarrhoeal diseases, which before were placed under diseases of the digestive organs. These modifications have been approved by the National Board of Health, and are now under consideration by the Committee of the College, which is engaged in the revision of the nomenclature.

After the compilation above referred to had been completed the slips were used to correct and complete the lists of deaths prepared by the enumerators. The blanks for these lists, which are known as the mortality schedules, differ from those used in previous censuses by having columns for the nativity of the father and mother of the decedent, the length of his residence in the county, the place where the disease was contracted, if not in the county, and the name of the attending physician. They also contain two supplementary schedules: one giving the names of those dying in the place, but belonging to families living in another county or State; the second giving names of persons belonging to families residing in the place, but who have died away from home in another county or State.

The first rough count shows that about 620,000 deaths have been returned upon these schedules. To these there will be added from the register slips above described about 50,000 deaths, and the records of the cities from which no enumerator's schedules are received will add about 80,000 more, making a total of about 750,000 deaths returned for the year, which, for a population of fifty million, give a death rate of fifteen

per thousand. While it is certain that this does not include all the deaths, it is evident that it is much more complete than previous censuses, — the total number of deaths for that of 1850 having been 323,098, being a mortality rate of 13.910 per thousand. In 1860 there were returned 394,153 deaths, being a mortality rate of 12.510 per thousand. Upon this last Professor Elliott constructed life tables, assuming a deficiency in returns of deaths of 41 per cent., or, in other words, that the true death-rate was a little over 18 per thousand. If this were assumed as the true death-rate for the last census year, the deficiency in returns would be less than ten per cent.

From this brief statement it will be seen that General Walker is to be congratulated upon the improvement which has been effected in the Tenth Census in regard to the completeness of the mortality statistics, and also that the medical profession of the country has contributed largely to the securing of this relative completeness.

In order to obtain as much information as possible with regard to the amount and distribution of the actual deficiencies in the mortality lists, the entire registers of deaths of two States and several large cities for the census year have been copied, and will be compared with the mortality schedules furnished by the census enumerators from the same localities. The results of this comparison will probably be interesting and valuable.

An attempt has been made in the Tenth Census to obtain the number of the population on the 1st of June who are so sick or disabled as to be unable to pursue their ordinary avocations, and also to give the causes of such sickness or disability. This attempt has never been made before in this country, and in other countries has only been systematically made, as far as I am aware, in the three censuses of Ireland for 1851, 1861, and 1871. It is too soon yet to speak of the results of this attempt, as the computations have not been made, but it is evident that either the returns will prove to be too imperfect to be of much, if any, statistical value, or amount of sickness is much smaller than has been usually supposed. Taking the State of Rhode Island, where the census was taken under the direction of a skilled superintendent, Dr. Snow, who had so small a territory to deal with that he could make sure of the knowledge and training of almost all his enumerators, and where it is to be presumed the population schedules have been filled out with the greatest accuracy and completeness, it is found by a count that the number reported sick and disabled, aside from those reported as blind, deaf and dumb, insane, crippled, etc., was a total of 3276 out of a population of 276,528, being in the ratio of 11.8 per thousand. Comparing this with the results of the Irish census of 1861, I find that the proportion of sick at their own homes reported in Ireland varied from 1 in 142 to 1 in 912 in the different localities specified, which is in the ratio of 7.01 and 1.06 per thousand respectively. It is usual to compute that for every case of death in a community there are two cases constantly sick.

It will be seen, if the estimate is correct, the Rhode Island census comes much more near completeness than that of Ireland. The only other source of comparison which I have thus far found available is that of the health of the army, in which I find that among the white troops for the year 1877 the average num-

ber constantly on the sick roll was 44 per thousand of mean strength.

Upon the whole, it seems probable that the results from the Rhode Island count are nearer the truth than any other data which we possess.

In conclusion, I think the Association will be glad to know that the work of tabulating these returns of deaths is going on rapidly, and that the results will be published in a form which will be found more satisfactory than the forms heretofore used, because it will present the comparison of mortality rates of countries and groups of countries as well as of entire States. The importance of these mortality records is very great, in fact, because for very large portions of this country they give almost the only positive data we can get for comparison of the truthfulness of different localities; in fact, because they will seem both as a pattern and an incentive for scientific work in this direction on the part of manufactures and States.

Dr. N. W. Davis, of Chicago, reported in behalf of a Committee on Atmospheric Conditions, and their Relations to the Prevalence of Disease. He recommended that a standing committee of five be appointed to take this extensive subject into consideration.

VI. OBSTETRICS AND DISEASES OF WOMEN. — The chair announced the following committees: —

Committee for Selection of Subject of Essay: Prof. E. S. Dunster, Michigan; Prof. G. M. B. Maughs, St. Louis; Dr. H. M. Field, Boston.

Committee of Award: Dr. Robert Battey, Georgia; Dr. Albert H. Smith, Philadelphia, Pa.; Dr. P. F. Mundé, New York city.

Committee to which Papers for Publication are referred: Dr. Joseph Tabor Johnson, Washington, D. C.; Dr. John Byrne, Brooklyn, N. Y.; Dr. H. P. C. Wilson, Baltimore, Md.

Dr. Joseph Tabor Johnson, of Washington, read a paper entitled Can we make a Positive Diagnosis of Pregnancy Previous to the Occurrence of the Audible Sounds of the Fœtal Heart and the Detection of the Fœtal Movements? He thought that in the softened condition of the cervix uteri and the pinkish color and increased temperature of the vagina we have quite a positive diagnostic evidence of pregnancy. It is admitted that the only positive and indisputable signs are determined by auscultation, ballottement, and fœtal movements; but these signs are not usually present in the first half of pregnancy. The presence of kiesteine in the urine, milk in the breast, the odor of vernix caseosa upon the finger as it is withdrawn from the vagina after a digital examination, the smooth condition of the anterior wall of the vagina and anterior cul de sac, associated with a pinkish-purple color of the vaginal mucous membrane, the placental souffle, the existence of *gravidene* in the urine, the presence of certain caseous elements resembling milk in the urine, were all passed in review as diagnostic signs of pregnancy; but no definitely stated conclusion was arrived at.

Dr. R. Beverly Cole, of San Francisco, did not hear the whole of Dr. Johnson's paper, but thought, from what he did hear, it was rather an interrogation than a treatise. He then stated that there were three physical signs of pregnancy which he relied upon chiefly, namely: (1) placental souffle; (2) pulsation of the cord; and (3) the sounds of the fœtal heart. He regarded the last as the best and most reliable of them all. The pulsations vary from 110 to 140, — double

that of the mother. He described the sound as resembling the ticking of a watch under a pillow. Dr. Cole thought no signs positive enough (generally) to justify one in giving *decided* opinions when consulted on this point.

Dr. Albert H. Smith, of Philadelphia, thought placental souffle the most unreliable of the signs mentioned by Dr. Cole. He was anxious, he said, to hear Dr. Joseph Tabor Johnson's results from the thermometric observations on the cervix uteri. He thought Dr. Johnson's suggestions in regard to the application of the telephonic principle to the uterine sound, and the use of the electric light for illuminating the vagina, very good, — quite brilliant, he would say. Liked the bi-manual method best of all.

Dr. Paul F. Mundé, of New York city, agreed with Dr. Smith. His favorite method was the bi-manual. He thought Dr. Smith had touched the key-note in making this statement. He thought that this method, taken with the other signs usually associated, would enable one to make out a case better than any other methods he knew of. He cited a case in support of his position.

Dr. Alexander Dunlap, of Ohio, agreed with Drs. A. H. Smith and Joseph Tabor Johnson. His method was the same, the bi-manual. The presence of fibroids may sometimes mislead, as they enlarge the womb, but they are generally hard when small; sometimes soft and dropsical when large, and rarely symmetrical. These points he thought it well to notice. Sanious discharge from the os is strong evidence of intra-uterine fibroid.

Dr. James M. Scott, of St. Louis, wanted to know if it was not a very difficult thing to use the bi-manual method on a fleshy patient, which was answered in the affirmative.

Prof. G. M. B. Maughs, of St. Louis, wanted to know if there were any signs by which we can tell if a woman is *not* pregnant. Dr. Maughs adhered to the original form of his query. He thought that we have an almost certain method, namely, the bi-manual, and that the measurement of the uterus laid down for the various weeks of pregnancy would enable us to determine after examining.

Prof. A. F. Erieh, of Baltimore, disagreed with Prof. G. M. B. Maughs, of St. Louis, on the ground that the standards of measurement are too variable. He thought the thermometric indications in the os uteri would prove of great value as an aid in diagnosis.

Dr. Robert Battey, of Georgia, arose, and stated that he was surprised that no gentleman had mentioned any of the following aphorisms, in doubtful cases: —

(1.) Always consider a married woman pregnant if living with her husband until *proved* otherwise.

(2.) Always consider an unmarried woman innocent till *proved* guilty.

(3.) Always believe that a woman married, of the highest character, living with a husband of equally high character, both solemnly assuring the medical man that no intercourse has taken place for two years, as she has been bed-ridden for that length of time, may bring forth a dead fœtus.

(4.) Always believe a young unmarried woman with abdominal tumor, of high social position and unimpeachable virtue, if she has been watched over by a platonic and abstemious young cousin of the male persuasion, while the mother went out, to be pregnant.

(Applause and laughter.)

Dr. James R. Chadwick (chairman), of Boston, drew a diagram on the board of the pelvic organs, and illustrated his methods of bi-manual examination.

Dr. Albert H. Smith, Philadelphia, drew a representation on the board of a thermometer made with an angle and guards for taking the temperature of the cervix.

Dr. J. R. Chadwick stated that he had noticed blueness of the vagina in many cases of pregnancy at various stages.

Dr. Alex. Dunlap, Ohio, is very careful about introducing the sound. He makes his digital examinations whilst the patient is standing.

Dr. Johnson asked Dr. Dunlap to give his experience as to the blue color of the vagina in cases of fibroids.

Dr. Dunlap said that as he rarely used the speculum he had none.

Dr. Paul F. Mundé, New York city, exhibited a curette for the removal of adherent placenta after abortion, designed by himself. He said he thought it best to remove the placenta reasonably soon, if it did not come away, in cases of abortion.

VII. PRACTICE OF MEDICINE. — The session opened with the reading of two papers on Pneumonia, one from Dr. Prentice, of Washington, and one by Dr. W. C. Dabney, of Virginia, both advocating the zymotic theory of the disease.

Dr. L. Duncan Bulkley, of New York, read a paper upon The Diet and Hygiene of Eczema. The paper was based almost wholly upon the experience of the writer. After calling attention to the effect which certain articles, as shell-fish, strawberries, bananas, etc., produced upon the skin of those who were peculiarly disposed thereto, in causing erythema and urticaria, and also the well-recognized eruptions from iodide and bromide of potassium, quinine, etc., he stated that in like manner articles of food and modes of life surely did produce cutaneous changes, and that the genesis and obstinacy of many cases of eczema rested upon errors which existed in nutrition from faulty diet and hygiene. Give perfect nutrition, and eczema disappears. The errors were not always apparent, and often required to be searched for.

In regard to the true meaning of dieting in this connection, he did not intend thereby a starvation process, but his definition of diet was as follows: "Such a regulation of the quantity and quality of the food and drink taken, its mode of preparation and time and method of consumption, as shall conduce to the restoration and maintenance of health."

Dr. Whittaker, of Cincinnati, read a paper on the Treatment of Diphtheria, taking the ground that diphtheria was first a local and afterwards a general disease; that it is only when the epithelial barrier is broken down that the blood and the body become infected. The essayist maintained that the poison passes over into the blood little by little, new quantities reinforcing the first installments, until the blood is super-saturated with the disease. The treatment of the poison at the local depot and neutralization of virus in the blood were both necessary.

Dr. Henry A. Martin, of Boston, read a paper upon the Variola Vaccinæ and Variola Equinæ in Massachusetts. He reported a series of cow-pox (which were, so far as he knew, the first authentic cases reported in this country) which were of great interest. He also reported a case of variola equinæ, the

seventh authentic case since the days of Jenner. In conclusion, he moved that this section recommend to the Association that a committee be appointed to visit the various farms and investigate the whole subject of bovine virus, as it was one subject to many and great abuses. The motion was carried.

FOURTH DAY. GENERAL SESSION.

The Association considered the amendment to the code of ethics.

Dr. J. S. Billings then offered the following substitute for the original:—

"It is not in accord with the interest of the public or the honor of the profession that any physician or medical teacher should examine or sign diplomas or certificates of proficiency for, or otherwise be specially concerned with, the graduation of persons whom they have good reason to believe intend to support and practice any exclusive and irregular system of medicine."

The substitute was adopted.

The committee on nominations reported the following additional officers, who were elected:—

Practice of Medicine: chairman, Dr. J. A. Oosterlony, Kentucky; secretary, Dr. Deering J. Roberts, Tennessee.

Surgery and Anatomy: chairman Dr. J. C. Hughes, Iowa; secretary, Dr. William A. Byrd, Illinois.

Obstetrics: chairman Dr. H. O. Marey, Massachusetts; secretary, Dr. C. V. Mottram, Kansas.

Medical Jurisprudence and State Medicine: chairman, Dr. A. L. Gihon, Washington, D. C.; secretary, Dr. J. H. Sears, Texas.

Ophthalmology, Otology, and Laryngology: chairman, Dr. D. B. St. John Roosa, New York; secretary, Dr. J. Solis Cohen, Philadelphia, Pa.

Diseases of Children: chairman, Dr. S. C. Busey, Washington, D. C.; secretary, Dr. William Lee, Baltimore, Md.

Dentistry: chairman, Dr. D. H. Goodwillie, New York; secretary, Dr. P. W. Brophy, Illinois.

Judicial Council: Drs. S. N. Benham, Pennsylvania; J. M. Toner, Washington, D. C.; D. A. Linthicum, Arkansas; William Brodie, Michigan; H. S. Holton, Vermont; A. B. Sloan, Missouri; R. Beverly Cole, California.

THE ASSOCIATION OF MEDICAL EDITORS.

The Association of Medical Editors met at Exchange Hotel on Monday evening, May 2d, at 8:30 o'clock. In the absence of Dr. J. F. Shrady, president, Dr. Oosterlony was called to the chair, Dr. D. S. Reynolds, secretary.

Dr. Shrady's address was read by Dr. Carpenter, and on motion it was ordered that the same be printed.

The committee on necrology (Drs. Dunster, Cole, and Edwards) was appointed. The committee reported the death of Drs. Davis and Cowling during the past year, and requested indulgence for the preparation of their report on memoirs, which was granted.

The committee on nominations reported as follows: president, Dr. Landon B. Edwards, Richmond, Va.; vice-president, Dr. Ralph Walsh, Washington; secretary, Dr. D. S. Reynolds, Louisville.

The Association adjourned to meet on the Monday evening preceding the annual meeting of the American Medical Association.

THE PENNSYLVANIA STATE MEDICAL SOCIETY.

THE thirty-second annual meeting of the State Medical Society at Lancaster, Pennsylvania (May 11th to 13th) was the largest ever held by that body, about two hundred and sixty-five delegates being present. Among the papers read were the usual addresses on recent advances in several departments of medicine, and reports upon special subjects, and about twenty essays upon various topics.

The Address in Medicine was delivered by Dr. J. Solis Cohen, of Philadelphia; it was practical in character, and contained some apposite remarks upon the free and indiscriminate use of new remedies, the physiological effects of which have not been established, and cited several cases in which such clinical experiments had produced dangerous symptoms. The Address in Surgery was delivered by Dr. S. M. Ross, of Blair County. The Address in Hygiene by Dr. B. Lee, of Philadelphia; in Obstetrics by Dr. S. T. Davis, of Lancaster; and in Mental Diseases by Dr. S. S. Schultz, of Danville. A number of practical papers upon miscellaneous subjects were discussed in the two daily sessions; and a very able annual address was delivered on the evening of the first day by the president, Dr. John T. Carpenter, of Schuylkill County.

A resolution memorializing the legislature, and insisting upon the appointment of female physicians in insane asylums, did not pass the association; the same fate met one permitting representation to the Philadelphia College of Physicians.

Considerable attention was paid to the necessity of preparatory education of medical students, very able communications upon this subject being presented by Dr. Traill Green, of Easton, and Dr. O. H. Allis, of Philadelphia. Every county medical society, by a standing resolution of the Pennsylvania State Society, is now obliged to have a board of examiners, whose duty is to examine into the qualifications of every young man desiring to study medicine previous to entering the office of a member of the society as his preceptor; and members are obliged to have their office students approved by such board of examiners under penalty of discipline.

The committee on the State Board of Health reported progress; there appears to be some hope that the bill now before the legislature may become a law, but it has not yet succeeded in obtaining the necessary authority.

The following officers were unanimously elected:—

President, Dr. J. L. Ziegler, of Mount Joy. Vice-presidents, Dr. Jos. A. Reed, of Allegheny; Dr. W. L. Roland, of York; Dr. J. W. Houston, of Chester; Dr. W. Murray Weideman, of Berks. Permanent secretary, Dr. W. B. Atkinson, of Philadelphia. Recording secretary, Dr. G. Thicksow, of Erie. Corresponding secretary, Dr. O. H. Allis, of Philadelphia. Treasurer, Dr. Benj. Lee, of Philadelphia.

Next place of meeting, Titusville, Crawford County, Pa., on the second Wednesday in May, 1882.

Recent Literature.

Lectures on Diseases of the Nervous System, especially in Women. By S. WEIR MITCHELL, M. D. Philadelphia: Henry C. Lea's Son & Co. 1881. Pp. 238.

The preface says: "The lectures which compose this volume deal chiefly with some of the rarer maladies, or forms of maladies, of women. Many of them are original studies of well-known diseases, and others deal with subjects which have been hitherto slighted in medical literature, or which are almost unknown to it."

Probably Dr. Mitchell is better qualified by experience than others to write upon these subjects, and he has certainly produced a very interesting book. The first chapter is devoted to the Paralysis of Hysteria. The author takes a thoroughly sensible view of the subject, does not have confidence in the possibility of speedy cures in all cases, but looks rather to "slow, steady, hopeful training of the will-powers through every-day effort, which needs some caution not to err in the way of excess."

Next follow chapters on Hysterical Motor Ataxia, Hysterical Paresis, Mimicry of Disease, Unusual Forms of Spasmodic Affection in Women, Tremor, Chronic Spasms, Chorea of Childhood. This latter chapter is devoted to a discussion of the meteorological conditions favorable to the outbreak of chorea. The largest number of cases were found to occur in March. Dr. Mitchell has also compared the frequency of chorea with the occurrence of storms, a subject which it would be interesting to pursue still further. He also refers to the frequency with which chorea recurs, and thinks that by giving arsenic in the spring he has prevented the recurrence.

The chapter on Habit Chorea is devoted to a subject not often referred to, excepting very incidentally, one which is very troublesome to both friends and physicians, though often the patient is singularly unconcerned in regard to the infirmity.

Disorders of Sleep in Nervous or Hysterical Persons is devoted to certain shocks occurring while the patient is falling asleep or during the earliest part of the night's rest, which are not only very annoying, but frequently give rise to great anxiety in the patient's mind, lest they should be precursory of more serious disturbance.

This chapter is of much interest, and would have been still more so if the author had given an explanation of these phenomena.

In the chapter on Hysterical Aphonia is recorded the method of teaching the patient to talk by beginning with sounding the simple vowels, having previously filled the lungs with air, and then advancing to consonants and more complex sounds.

The book closes with a chapter on Treatment by Seclusion, Rest, etc., in which the author gives his latest views in regard to such treatment. In this chapter there is not much variation from the opinions and directions given in *Fat and Blood*. Dr. Mitchell emphasizes the importance of having a good nurse, and that the nurse and patient should harmonize with each other. This is a very essential point in the treatment of such cases.

Such is, in brief, the object of the book and the general scope of its teachings. A short notice cannot do justice to the book; there are many valuable hints in regard to diagnosis and treatment scattered through the work.

It might be more interesting, perhaps not more useful, if greater attention had been given to a fuller consideration of the nature of some of the affections described.

S. G. W.

Diseases of Children. By DR. WM. HENRY DAY, F. R. C. P., London, Physician to the Samaritan Hospital for Women and Children. Second edition, revised and enlarged. 8vo, 752 pages. Philadelphia: Presley Blakiston, No. 1012 Walnut Street. 1881.

Dr. Day has been a frequent contributor to the different English medical journals, and is also known as the author of a book entitled *Headaches, their Causes, Nature, and Treatment*, which has been well received by the profession, and has already reached its third edition. The present work has rapidly reached a second edition, and from the date of the author's preface we infer that the American edition appears simultaneously with its publication in England. Dr. Day brings to his task a large experience, and evidences a very thorough knowledge of the literature, native and foreign, pertaining to this special branch of medicine. One of the notable features in this treatise is the very large use made by the author of extracts and quotations from the works of others, and from articles taken from the medical journals, which his wide and varied reading has placed at his disposal, and which, as a rule, have been carefully and judiciously selected. The references are always most punctiliously given, and while the work may not have the same stamp of originality that has marked other similar works that might be named, we think that in the present case it would be detrimental to its usefulness were this feature not a prominent one.

There is a good index at the end of the book, and also a descriptive heading before each chapter.

There are, for those who desire such aid, ninety-four prescriptions to be found interspersed through the pages, and these have been collected together at the end of the book, numbered in the order in which they follow each other, and also have set against each "formula" the page on which they are found.

We find the usual preliminary chapters in this case under the head of Introductory Remarks, Milk Diet and Hygiene, and Acute and Chronic Disease, after which follows the consideration of the special diseases.

We confess to a feeling of dissatisfaction with much that the author has to say upon the treatment of children's diseases. There is a too great readiness to resort to active and powerful drugs; there is not enough credited to the natural history of disease, and a want of appreciation of the part self-limitation plays in many acute diseases, as well as a desire to intervene too much for the purpose of "expediting the different stages."

It savors of a time which we thought had long gone by to read in the treatment of acute disease, page 56:—

"The remedies we employ are, as a rule (at least at an early stage), antiphlogistic and eliminative, such as venesection and the use of calomel and antimony."

Tartarated antimony is spoken of in croup as "our sheet anchor for its effect in producing free and speedy vomiting," to be followed, if there be much febrile excitement and disordered *prima via*, by one grain of calomel every four hours, or one full dose for the purpose of emptying the bowels and controlling the fever; and in the fibrinous form, when there is violent and acute inflammation, with a firm, hard pulse, and a full reserve of strength, two or three leeches may be applied over the xiphoid cartilage." (Page 332.) Tartar emetic is spoken of as "a most useful drug" in the treatment of pneumonia, given to children, when strong, for a

short time, in doses of one twelfth to one sixth of a grain. With the tendency to exudation of lymph mercury is said, "as an antiphlogistic to shorten the stage of exudation and promote and shorten the absorption of the newly-effused lymph before it has had time to become organized, and to act as an irritant to the surrounding healthy structures." Small doses of calomel and James's powder are recommended for this purpose.

In the treatment of pleurisy, while a small dose of antimony at the beginning, every four hours, is recommended, to be added to the solution of acetate of ammonia and a few drops of laudanum, as lowering the pulse and promoting diaphoresis, he adds at the same time that it "is far less beneficial than in pneumonia; and unless the case is complicated with the latter affection it is quite secondary to calomel and opium." (Page 435.)

"Calomel with Dover's powder," he writes, "is a good combination;" and if there is not much pain the mercurial may be given with nitrate of potash and James's (antimonial) powder."

In the author's recommendation of the employment of tincture of aconite, as advocated by Ringer, in various febrile diseases, especially in scarlatina, tonsillitis, and sore throat, it should be remembered that the preparation of the United States Pharmacopœia is between two and three times stronger than that of the British. This precaution is particularly necessary, as the dose prescribed by him of half a minim (one drop) every hour or half hour would be unsafe unless with older children and under a most careful watching.

There are but few errors to notice among the prescriptions. In Formula 24, page 185, 3i. should read ʒi. In Formula 57, page 379, *ad* should read *aa*. In the list at the end of the book, Formula 32, *Acid. nucis vom.* should be *Tinct. nucis vom.* In the same list, Formula 42, *Aquæ ad ʒiv.* should read *Aquæ ad ʒiv.* The author describes the "compound phosphorated cod-liver oil" of Savory and Moore, which is recommended by him in the treatment of phthisis pulmonalis. (Page 521), as containing in each fluid drachm one grain of iodine, two grains of bromine, and one fortieth of a grain of phosphorus. This must, of course, be a mistake.

The book has been written with great care, and the author is a good writer. The publisher's part of the task has also been excellently performed.

Mr. Spencer Wells's Note-Book for Cases of Ovarian and other Abdominal Tumors. London: J. and A. Churchill, New Burlington Street. 1881.

A new edition (the sixth) of Mr. Wells's Note-Book for recording cases of ovarian tumors is just published. To a surgeon who operates for the removal of abdominal growths this little book is very valuable. It saves time, and when filled out describes the case so that the diagnosis is much more easy; besides, when the case books are filled and accumulate they can be bound and preserved, a ready book for reference, as well as a very useful one to lend a nurse in charge of her first case of ovariectomy. The only alteration in the book is the substitution of a better diagram on page 3, and a note in regard to whether spray is used. Since 1878, when Mr. Wells began to use spray, he has had 137 cases of ovariectomy, with 13 deaths, a mortality of 9.4 per cent.

Medical and Surgical Journal.

THURSDAY, JUNE 2, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

THE CELEBRATION OF THE CENTENNIAL ANNIVERSARY OF THE MASSACHUSETTS MEDICAL SOCIETY.

IN the last issue of the JOURNAL attention was called to the measures adopted for the reception and entertainment of the members of the Massachusetts Medical Society who may attend the approaching centennial anniversary. The committee of arrangements of the society desire again especially to emphasize the following details.

It is especially important that members should bring their tickets of invitation, already sent out with the programmes, as no duplicates are issued.

Tuesday, June 7th. The special train for Brighton will leave the Boston and Albany station, Beach Street, at 8.45 A. M. precisely, and the Columbus Avenue station two minutes later. Visitors to Cambridge take the horse-cars from Bowdoin Square, Boston.

Guides will be stationed at Quincy Street and Harvard Square, Cambridge, and at the various points of interest.

The doors of Sanders Theatre will be open to the society and to the public at 10.30 A. M., and the centennial oration will be delivered at eleven o'clock.

At 12.45 P. M. cars will be in waiting at Memorial Hall, and will start immediately for Bowdoin Square, where barges will be in readiness to convey members of the society to Rowe's wharf, whence the steamer will start at two P. M., or upon the arrival of the last barge from Bowdoin Square.

The harbor excursion has been so arranged that the steamer will reach Boston on its return as early as 6.30 P. M.

Wednesday, June 8th. The tickets of invitation give free admission to the Art Museum in the morning.

The Museum of the Boston Society of Natural History, the Institute of Technology, Trinity Church, and the historical exhibition in Horticultural Hall will be open to members of the society from nine A. M.

The latter exhibition will be one of especial interest, and will well repay careful inspection.

At twelve M. the doors of Horticultural Hall will be closed, and will remain closed during the delivery of the oration. When opened at the conclusion of the oration members are requested to enter the hall and join the procession, as called by classes, to the dinner, as by so doing they will assist in avoiding the confusion incident to a crowd at the Music Hall entrance.

AN HISTORICAL AND COMPARATIVE EXHIBITION OF MEDICAL INSTRUMENTS AND BOOKS AND OF MEDICINES.

TO many, one of the most attractive and interesting features of the celebration of the one hundredth anniversary of the Massachusetts Medical Society will be the comparative and historical exhibition of instruments, apparatus, books, and medicines which will be open to visitors at nine o'clock Wednesday morning, June 8th, in lower Horticultural Hall. The Metric Bureau will also contribute to this exhibition. The collection of apparatus and of surgical instruments is in charge of Drs. J. O. Green and E. H. Bradford, and is designed to illustrate the progress made in this direction within the past century, embracing, as it will, the old and the new.

The collection of books, which it is thought will be particularly fine, is in charge of Dr. David Hunt, and will be confined to old and rare medical works.

The contemplated display in materia medica and pharmacy will illustrate the advance in these departments during the past century. It is in charge of Dr. Wm. P. Bolles, and will consist of:—

(1.) A collection of drugs, showing; *a*, those which have been in use during the entire century; *b*, those discarded; and *c*, those introduced during the same time.

(2.) Active principles, with the dates of their discoveries.

(3.) Illustrative modern preparations.

(4.) Novelties: *a*, drugs, *b*, preparations.

(5.) Ephemeral drugs.

(6.) Obsolete mixtures and pharmaceutical curiosities. This scheme does not include instruments or mechanical appliances; these will form a separate feature in the exhibition, and are in the care of other hands.

(7.) Medicinal plants, living, pressed, and painted.

The cabinets of the medical department of Harvard University and of the Massachusetts College of Pharmacy will form the basis of the exhibition, and it will be completed by donations (of which many are already promised) and by purchase. These additions, after the anniversary is over, unless their disposal is especially provided for by the donors, will be kept for the benefit of the institutions above mentioned.

From the Botanic Garden and the Herbarium at Cambridge a fine display of living and pressed medicinal plants is expected.

The bottles and labels are to be uniform, and will be provided by the society.

It will be seen from the above plan that the exhibition is to be purely historical and scientific in character, and that it must be restricted to such proportions as are consistent with this object. Every form of advertising will be necessarily excluded.

A card or bulletin will be displayed, upon which a courteous acknowledgment to contributors will be made.

Members of the society are advised not to omit visiting this exhibition, forming, as it will, both a novel and very instructive feature of the celebration.

RESISTANCE TO TYRANTS IS OBEDIENCE TO GOD.

To whom it may concern, but especially to members of the Massachusetts Medical Society:—

A despot! and an oligarchy! having conspired how not to do it, and a certain number of irresponsible members of the Massachusetts Medical Society having announced on a slip prefixed to the first page of the JOURNAL that they will do it, we think some asperities may be softened, and the minds of our readers be cleared up by the reproduction of the following extracts from the society's records:—

"Councilors' Proceedings, June 8, 1880: Dr. Bronson requested the president to rule upon the following: Can a question now upon the table of the councilors, *if taken therefrom and acted upon affirmatively during the current year*, be also acted upon at an adjourned meeting of the society from to-morrow? The president replied that it could.

"Society's Proceedings, June 9, 1880: Dr. Bronson stated that a question was *now pending before the councilors*, namely, that of the admission of women to the society, on which the councilors might take such action during the coming year *as would require the concurrent vote of the society*. In view of such a contingency, and to meet it, *should it arise*, he offered the following:—

"*Voted*, That when this meeting adjourn it does so to meet at the place of annual meeting on Tuesday preceding the annual meeting of 1881, at four o'clock, P. M.

"After discussion the motion of Dr. Bronson was adopted. A true copy. Attest: F. W. Goss,

Recording Secretary."

The contingency above referred to did not arise, the councilors not having voted on the question, and it certainly seems very desirable that the subject of despotism and that of women should be kept distinctly separate, as far as the incorporated body known as our State Medical Society is concerned, whatever may be the unfortunate association between these words in the minds of some members in connection with the small organization known as the family.

MEDICAL NOTES.

—Subscribers who desire to do so can pay their subscriptions at the coming meeting of the Massachusetts Medical Society, June 8th.

THE LATIN INSCRIPTION ON DR. J. B. S. JACKSON'S PORTRAIT. A CORRECTION.

—As a number of errors found their way into the type of the Latin inscription on the portrait of J. B. S. Jackson as given in the report of the meeting of the Improvement Society in our last issue, we reproduce the inscription entire:—

JOHANNES B. S. JACKSON, M. D.,
Anatomici Pathologici Præstantiss., Anatomie Pathologicæ
Prof. Harv., Musculi Pathologici conitoris, Societatis
pro Medicina Progressu constituta decoris et præ
sidi, Hunc typhum Solatus ejus gratia
Memoriæ dedit.
A. D. MDCCCXXXI

—The Washington Training School for Nurses held their graduating exercises in the Congregational

Church, Tuesday evening, the 24th instant. The church was packed with an audience of interested people to witness the conferring of certificates upon the first class of graduates from this institution. The president of the society, Dr. Toner, presided, and opened the exercises by an appropriate address, giving such an interesting history of this institution that we give it in full. On the conclusion of these remarks, Dr. William Lee, a member of the medical faculty of the training school, made a very felicitous address, contrasting the efficiency of "Sairy Gamp" in the sick-room with that of the trained hospital nurse of to-day.

NEW YORK.

—Several important bills, from a sanitary point of view, have recently been passed by the legislature. Among them is the act to secure the registration of plumbers, and the inspection of plumbing and drainage in the cities of New York and Brooklyn, which provides for the registration of all plumbers, in order that the artisans engaged in this important branch of industry can be relied upon by the community as being qualified to perform the duties of their vocation, and that prior to the construction of new buildings plans for plumbing the same shall be submitted to and approved by the boards of health of New York and Brooklyn. Other bills passed were: the act conferring upon the State Charities Aid Association the power to visit and inspect any of the state, county, or town charitable institutions in the State, which has been pending for some time; and an act to promote the health of female employees, which makes it a misdemeanor not to provide and maintain suitable seats for the use of women employed in mercantile establishments, and directs that they shall be allowed to remain seated for a reasonable time each day.

—The committee on experimental medicine of the State Medical Society, which includes the names of such men as Drs. James R. Wood and Willard Parker, of New York, Joseph C. Hutchinson, of Brooklyn, S. O. Vanderpoel, of Albany, and H. D. Didama, of Syracuse, and which was especially appointed for the purpose of protecting experimental investigations from harmful interference, has addressed a communication to the Society for the Prevention of Cruelty to Animals, in which they protest against such interference on the part of the latter society in the matter of vivisection. In it they set forth that should the efforts made in the name of the society succeed in preventing this by legal enactment, a lasting detriment to the cultivation and improvement of medicine would ensue; that the experiments in question are not performed in a spirit of wanton cruelty, nor in such a way as to inflict needless suffering upon the animals employed; and that the information acquired by their means is often of the highest value for the protection of life and property.

—The hot weather that occurred during the week ending May 11th had a very appreciable effect upon the mortality of the city, and the deaths for the week reached the very high figure of eight hundred and twenty-two.

Miscellany.

"UNNECESSARY OPERATIONS IN UTERINE SURGERY."

MR. EDITOR, — I have read with much interest the admirable paper On Unnecessary Surgical Operations in the Treatment of the Diseases of Women, by Clifton E. Wing, M. D., recently published in the JOURNAL. With the doctrines therein enunciated I fully concur. His statement that "*lacerations involving the sphincter muscle and the rectum*" (the italics are Dr. Wing's) "of course always demand operative measures" prompts me to relate a case which happened in my own practice. June 17, 1877, I attended a little lady in her first labor. I say advisedly a *little* lady, as her normal weight was but eighty pounds. Although of such diminutive size, she was plump, admirably proportioned, a little model of perfect womanhood. The head had for some time lain low in the excavation; the perinæum was fully distended, but the vulva refused to dilate. I applied my forceps, and just as the head was emerging from the outlet she suddenly threw up the pelvis (thus altering the line of traction), the thin distended tissues gave way, and a fearful laceration was the result. Perineal resistance was so completely done away with that not only the head, but the whole body of the child, as it were, *dropped* out. The child weighed nine pounds and four ounces. Not only was the perinæum torn throughout its whole extent, but also the sphincter ani, and the rent extended fully two inches up the rectum, causing very profuse hemorrhage from the hemorrhoidal veins. I frankly told the patient and her husband what had happened; explained to them the nature of the injury and its extent, and that at some future time it would necessitate a surgical operation. So perfectly was all control of the bowels lost that for many days when she would have a passage from the bowels, so hard that it could be taken up in the fingers, the first intimation she would have of its presence would be by the scent. The injury was of such extent I deemed anything short of an operative procedure utterly useless, and so did absolutely nothing, save directing the nurse to keep the wound clean. I did not even tie her knees together. To my surprise and delight the wound soon filled with healthy granulations, and in less than two months it was perfectly healed, the normal action of the sphincter restored, and the woman as well as ever. May 10, 1878, I again attended her in confinement, when, after an easy labor and without the slightest difficulty, she gave birth to a child weighing nine pounds and twelve ounces. Scarcely any trace of cicatrix from the laceration could be discovered.

T. C. WALLACE, M. D.

CAMBRIDGE, N. Y., May 17, 1881.

LETTER FROM LEIPSIC.

MR. EDITOR, — Prof. Karl Thiersch, of Leipsic, recently presented in his clinic three cases of extirpation of the larynx for carcinoma. The results were different in the three cases, and seem sufficiently interesting to be reported. In one case recovery is complete, and there are no signs of recurrent disease, after a lapse of ten months. Another case is still living, three months after the extirpation, but has large recurrent growths, and will soon die. A third case died of pneumonia three or four days after the extirpation. The

method of operation was essentially the same in each case, and need be detailed but once.

The patient was a woman, fifty-seven years old. For a considerable time past she had had great difficulty in swallowing, but could breathe well. Examination externally showed the larynx to be widened, but there were no enlarged lymph glands to be felt. Examination with the laryngoscope showed a growth in the lower part of the pharynx, rough and villous, looking like cancer. How far down into the œsophagus it extended could not be determined. A sound could not easily be passed into the œsophagus. The epiglottis and anterior part of the larynx were normal, and a view could be obtained with the laryngoscope down into the trachea. The membrane covering the arytenoids and that in the sinus pyriformis was œdematous, but showed no foreign growth. On December 9th tracheotomy was performed low down, below the isthmus of the thyroid gland, that the patient might become accustomed to the tube before the larynx was extirpated. Five weeks later the operation for the removal of the larynx was performed. A Trendelenburg tampon tracheotomy tube was inserted into the trachea, which prevented blood entering the lungs. This tube is constructed with two walls. The inner is continuous; the outer has an opening in its side. About the tube, and inclosing this opening, is tied a membrane of rubber; so that when inflated through a rubber tube connected with an opening at the upper part of the cavity, between the double-walled tracheal tube, the membrane can be inflated, filling the trachea so as to prevent the entrance of blood into it. An incision was made from one half inch below the chin to within one half inch of the tracheal tube, and transverse incisions were made from the upper extremity of this incision to the angle of the jaw, and from the lower extremity outward for about two inches on either side.

The sterno-hyoid and thyroid muscles were then dissected away, the inferior thyroid arteries were tied, and the trachea was divided at about two inches above the sternum, not so low, however, as the opening for the tracheal tube. The larynx with the thyroid gland was dissected free from the œsophagus, but at the upper part of the larynx the new growth was found to connect the two, so the œsophagus was also divided. The superior thyroid arteries were tied, and the pharynx and larynx were removed up to a level with the hyoid bone. The growth was found to extend downward in the œsophagus, so that this was cut away down to the same point at which the trachea had been divided, beyond which point the œsophagus appeared to be healthy. During the operation there was no severe hemorrhage. The common carotid and first part of the external carotid on either side were fully exposed for about four inches. A rubber tube, about three eighths inch in diameter, and sufficiently long to reach the stomach, was inserted into the œsophagus, and held in place by a thread passed through the rubber tube, and hung over the tracheal tube. The flaps of the wound were laid in place, stitched together, and drainage tubes were laid under them. The patient, chloroformed badly at first, wholly stopped breathing twice, but revived after performing artificial respiration for a short time. The day after the operation the patient was apparently in good condition, and was doing well. The day following she developed pneumonia, and a day or two later died. The post-mortem examination showed that the patient had died from pneumonia, re-

sulting from the inhalation of foreign substances into the lungs. This had been prevented, as was supposed, during the operation by the double tracheotomy tube, with the inflated membrane filling the trachea, but had occurred subsequently through the divided end of the trachea.

The patient whose recovery was complete is a man fifty-two years of age. He had had difficulty in breathing for about five years previous to operation, and this had gradually increased until it had become very great. On March 3, 1880, tracheotomy was performed, preparatory to the operation for extirpation. On April 15th the larynx was extirpated. The patient made a good recovery from the operation, and on February 8, 1881, ten months later, was shown in the clinic. The patient looks well, has a good appetite, can work, and shows no signs of recurrent disease, and is apparently cured. He can talk, breathe through his nose, and eat in the normal manner. The connection of the mouth with the trachea and œsophagus is accomplished by means of a peculiarly constructed tube. After the incisions for the removal of the larynx have nearly closed, there still remain three openings: one into the trachea, which holds the tracheal tube; one at the upper extremity of the divided œsophagus, which holds the long tube going into the patient's stomach, and through which he is fed; a third opening leads upward into the pharynx, through which the saliva constantly runs down upon the neck. When the parts are healed a tube is inserted into the openings. This tube differs from a common tracheotomy tube. To an ordinary tube is added another part bending upward from the part of the tube which projects externally from the trachea, just as the part which is inserted into the trachea bends downward. These two tubes (namely, those bending upward and downward in the same manner and with the same curves) open into the part of the tube projecting forward. The anterior part thus becomes common to both tubes. If a cork is placed in the part of the tube projecting anteriorly the patient breathes through his nose in the usual manner, the air entering the tube which projects upward into the pharynx, and passing downward into the trachea. If the cork is removed from the anterior portion of the tube the patient breathes as do other patients who have had tracheotomy performed. When the patient swallows, the food passes behind the tube going up to the pharynx, and enters the upper divided end of the œsophagus. To prevent foreign bodies entering the lungs when the patient eats or drinks the cork is removed from the portion of the tube projecting anteriorly. Thus the small amount of matter entering the tube projecting into the larynx comes out at its anterior opening. Solids give very little trouble, and when fluids are swallowed very little enters the pharyngeal tube. Over the end of the tube extending up into the pharynx are fastened two pieces of rubber tissue, the edges of which are parallel to and separated from each other but a short distance, and resemble, and in fact take the place of, vocal cords, so that the air passing between them produces a distinctly audible sound. The patient talks quite distinctly, but there is no modulation of the voice. His talking reminds one of an intoned service heard from a distant corner of a large cathedral.

A third patient mentioned is a woman, forty years of age. Three months have elapsed since the larynx was extirpated, but there have been recurrent growths, which must soon destroy the patient. The operation

was done after the usual method, tracheotomy having previously been performed. The patient did well, and was fed by means of the rubber tube, which remained constantly in the œsophagus, being long enough to reach the stomach. The patient was fed daily one and one half litre milk, six eggs, three hundred grammes leguminous soup, with wine, beer, and coffee. The œsophageal and tracheal tubes were removed from time to time to be cleaned, and also for the purpose of cleansing and dressing the wound, since there was constantly more or less saliva present, which flowed downward into the wound through the opening upward into the pharynx. After the operation the general condition of the patient improved, and she was much better nourished. Recurrent growths have repeatedly occurred, however, and for their removal there have been four or five subsequent operations. At one of these the external carotid of the right side was ligated, and a portion removed. In spite of the secondary operations the cancerous growths have continued to recur, and have now become so deep seated that further operative interference is impossible, and the patient cannot long survive.

The operation for the extirpation of the larynx and pharynx is a desperate measure, but would seem to be warranted. Of the three cases cited one has recovered, and cases of recovery are recorded by other surgeons. Without operative interference the patient is sure to die, and most cases coming to operation are in such a desperate condition that without operation death must occur very soon, unless the patient could be preserved by tracheotomy to prevent asphyxia, and an artificial opening into the stomach through which the patient could be fed. The dangers of the operation are chiefly from mediastinal abscess and pneumonia following the inhalation of foreign substances. If the cancer is confined to the larynx, so that the removal of the upper part of the œsophagus is not also necessitated, the dangers of operation are greatly diminished, as would also be the case were operative measures instituted before the growth had become greatly extended, and the glands of the neck thoroughly infected with the disease.

DUDLEY P. ALLEN, M. D.

THE LIBEL SUIT AGAINST THE BRITISH MEDICAL JOURNAL.

COPIES of the *Irish Times* containing a full report of the libel case of *Crawford v. The British Medical Journal* and *Cork Constitution* have reached us. This suit was brought by the plaintiff, the father of the child with suppressed scarlatina, to whom a dose of pilocarpin was administered in the Cork Fever Hospital by order of Dr. Maenaughton Jones, on account of the comment of the defendants upon the previous persecutions of Dr. Jones by the plaintiff. The jury was unable to agree. The *Times* makes the following remarks on the case:

"The Cork medical libel case has ended in a disagreement of the jury, and it is to be hoped that the public has heard the last of it. A more profitless feud than that which has divided the people of Cork into two factions for the last few months has seldom come under our observation. When the plaintiff first moved in the matter of the treatment to which his child had been subjected, there is every reason to believe that he was simply actuated by a desire to ascertain the facts and see justice done, and that he was without any special animus against the medical

practitioner, to whose practice he had been induced to ascribe the fatal result of the child's illness. After a time, however, the guilt of Dr. Jones seems to have become a fixed idea with him, irremovable by any process of reasoning or any weight of evidence. Some allowance must be made for a man so sorely tried as Mr. Crawford had been, but it is impossible also to be without sympathy for a practicing physician, who found himself the object of persistent attacks calculated to injure him materially, and unjustified by any serious argument. We think we express the views of most intelligent persons who have followed the whole story, when we say that it is probable Mr. Crawford's child would have died in any case, and that there were reasons for supposing that the drug administered might have a good effect. This being admitted, the systematic set made on Dr. Jones was utterly inexcusable. If we make an exception in favor of the bereaved father, we can make none in the case of those who joined with him and encouraged him. The comments made on the affair in the *British Medical Journal* were exactly such as might have been expected from an organ of the medical profession. The annoyance to which Dr. Jones was subjected was denounced in very severe and trenchant terms, which certainly, however, only expressed in plain language the views which such a paper was in a measure bound to advocate in the interest of the class

of professional men among whom it circulates. It is far from being clear that Mr. Hart's uncomplimentary references were aimed specially at the plaintiff in the trial under notice. We rather think they were intended principally for others. But even if the strong language of the *British Medical Journal* was meant to apply exclusively to Mr. Crawford, it would be a very dangerous precedent to make it the basis of a conviction for libel. To the paper the subject was one of the very highest importance, which it could not afford to pass over, and on which it was bound to express a strong opinion. On the other hand, the injury inflicted on the plaintiff by an unfavorable article appearing in a professional journal published in London could be only infinitesimal. If we were to take the facts of the story merely from the very clear charge of Mr. Justice Barry, and without reference to our previous knowledge of the affair, we should be inclined to blame the jury for not bringing in an almost immediate verdict of acquittal. And even with our belief in the sincerity with which Mr. Crawford took up the matter, and with our conviction that there was at least no "malignity" on his part, we do not see how a sensible jury could have found against a journalist for having used a word a shade too strong in denouncing what he sincerely believed to be the most unjustifiable persecution of a member of the profession of whose rights he was the champion.

REPORTED MORTALITY FOR THE WEEK ENDING MAY 21, 1881.

Deaths reported 2156 (no reports from Chicago or Milwaukee); 932 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 573, consumption 367, lung diseases 232, diphtheria and croup 133, diarrhoeal diseases 104, scarlet fever 89, cerebro-spinal meningitis 53, small-pox 50, measles 36, typhoid fever 28, malarial fevers 21, erysipelas 20, puerperal fever 15, typhus fever 14, whooping-cough ten. From *cerebro-spinal meningitis*, New York 20, St. Louis 14, Pittsburgh four, Cincinnati and Worcester three, District of Columbia and Buffalo two, Philadelphia, Baltimore, Providence, New Haven and Fall River one. From *small-pox*, Philadelphia 23, New York 20, Adams three, Brooklyn two, Cincinnati and Pittsburgh one. From *measles*, New York 13, Cincinnati six, Baltimore five, Pittsburgh three, New Orleans and Buffalo two, Philadelphia, Providence, Lowell, Worcester, and Westborough one. From *typhoid fever*, New York eight, Philadelphia five, Boston and Baltimore three, Pittsburgh two, St. Louis, New Orleans, District of Columbia, Lowell, Chelsea, Newburyport, and Adams one. From *malarial fevers*, New York eight, St. Louis, New Orleans, and District of Columbia three, Brooklyn, Baltimore, Cincinnati, and Nashville one. From *erysipelas*, New York four, Boston, Fall River, and New Bedford two, Philadelphia, Brooklyn, St. Louis, Baltimore, New Orleans, Providence, Worcester, Cambridge, Salem, and Haverhill one. From *puerperal fever*, New York six, St. Louis two, Brooklyn, Boston, New Orleans, Providence, Attleborough, Spencer, and Holliston one. From *typhus fever*, New York 10, Buffalo four. From *whooping-cough*, New York and Philadelphia three, Brooklyn two, Cincinnati and Spencer one. The mortality from cerebro-spinal meningitis has decreased from 88 for the week ending May 14th to 53.

Nineteen cases of small-pox were reported in Brooklyn, seven in Pittsburgh, two in New Haven, one in Cambridge, one in Brookline; one case of varioloid in St. Louis and two in Adams; diphtheria 37, scarlet fever seven in Boston.

In 43 cities and towns of Massachusetts, with a population of 1,067,781 (population of the State 1,783,086), the total death-rate for the week was 18.90, against 21.09 and 20.99 for the previous two weeks.

For the week ending April 30th, in 149 German cities and towns, with an estimated population of 7,813,015, the death-rate was 27.3. Deaths reported 4099; under five 1732; pulmonary consumption 673, acute diseases of the respiratory organs 476, diphtheria and croup 153, diarrhoeal diseases 121, scarlet fever 75, typhoid fever 58, whooping-cough 34, measles and 16theln 28, puerperal fever 21, typhus fever (Königsberg five, Stargard three, Memel two, Bromberg, Erfurt, Nordhausen, Gotha two), 15, small-pox (Königsberg two, Munich, Berlin five, Aachen four) 12. The death-rates ranged from 15.6 in Mannheim to 44.1 in Munich; Königsberg 32.1; Breslau 29.4; Dresden 22.9; Berlin 27.4; Leipzig 23.3; Hamburg 26; Hanover 20.3; Bremen 25; Cologne 32; Frankfurt 28.5; Strassburg 25.9.

For the week ending May 7th in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 20.1. Deaths reported 2929; acute diseases of the respiratory organs (London) 297, measles 105, small-pox (London 88) 89, whooping-cough 76, scarlet fever 56, diarrhoea 31, fever 31, diphtheria 22. The death-rates ranged from 12.4 in Brighton to 28.5 in Wolverhampton; Birmingham 16.5; Bristol 17.8; Manchester 19.9; Sheffield 20; Leeds 20.6; London 20.7; Liverpool 22.1. In Edinburgh 20.1; Glasgow 21.2; Dublin 27.5.

In the 21 chief towns in Switzerland, for the week ending May 7th, population 479,934, there were 29 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 23, measles nine, diphtheria and croup eight, whooping-cough three, typhoid fever two, scarlet fever one, puerperal fever one. The death-rates were: Geneva 22; Zurich 27.1; Basle 28.5; Bern 38.6.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DETIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 21, 1881, TO MAY 27, 1881.

Byrth, D., major and surgeon. His leave of absence for one month, on account of sickness, extended one month. S. O. 79, Division of the Pacific, and Department of California, May 17, 1881.

Meacham, F., captain and assistant surgeon. Relieved from duty at Fort Hamilton and assigned to duty as post surgeon, Fort Wadsworth, New York Harbor, relieving Assistant Surgeon Burton. S. O. 70, Department of the East, May 20, 1881.

Woodbury, E., captain and assistant surgeon. Now awaiting orders in New York city, to report to commanding officer, Wadsworth Point, N. Y., to relieve Surgeon Clements. S. O. 116, A. G. O., May 21, 1881.

Shannon, William C., captain and assistant surgeon. Assigned to duty at Fort D. A. Russell, Wyoming. S. O. 44, Department of the East, May 21, 1881.

Burton, H. G., first lieutenant and assistant surgeon. Assigned to temporary duty at Fort Hamilton, New York Harbor. S. O. 90, Department of the East, May 20, 1881.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the society will be held on Monday evening, June 6th, at eight o'clock, in the hall of the Medical Library Association, 19 Boylston Place. Reader, Dr. Inches. Subject, A Case of Gangrene of the Lung.

M. H. Richardson, M. D., Secretary.

CORRECTION. — The pressures under which the sphygmographic tracings, published with the first part of Dr. Reich's paper (page 466), were made were respectively as follows: 1, 50 grammes; 2, 50 grammes; 3, 250 grammes; 4, 150 grammes.

CORRECTION. — We are requested to state that the confirmation of his opinion quoted by Dr. Harris in the report of the Suffolk District Society, published in the JOURNAL of April 14th, was not given by the senior counsel in the case.

THE SEVENTIETH ANNUAL MEETING OF THE RHODE ISLAND MEDICAL SOCIETY will be held in Lyceum Hall, 62 Westminster St., Providence, on Wednesday, June 8, 1881. Exercises commence at ten a. m. The annual address by the president of the Society, Dr. Charles O'Leary, will be delivered at one p. m. The annual dinner will be served at the City Hotel at 2.15 p. m., Dr. L. F. C. Garvin, anniversary chairman.

PORTIONS OF THE CENTENNIAL ADDRESS
BEFORE THE MASSACHUSETTS MEDICAL
SOCIETY, JUNE 7, 1881.¹

BY SAMUEL A. GREEN, M. D.

I. THE Massachusetts Medical Society is about to enter upon the second century of its existence. Following the customs of this centennial period, it proposes to celebrate the anniversary of its origin by the story of its life. It was born in troublous times; and its founders were still engaged more or less actively in a political struggle which even to-day, by reflex action, is exerting a powerful influence on the events of the world. It was during the War for Independence that the physicians and surgeons of this Commonwealth were led to feel the need of some association in order to encourage professional studies. A new field was then opened for medical investigations, and the workers were eager to cultivate it. At no previous time had so many medical men of the State been brought into close relations with one another, or in contact with their brethren from other States; and this intercourse necessarily stimulated inquiry and discussion, and produced a community of professional feeling, such as had never before existed. In union there is strength; this was true in war, and it was true in peace. They saw that better results were accomplished by concerted action than by individual effort; and they were then ready to associate themselves together for the purpose of improving the practice of medicine and raising the standard of its study. It is a singular fact in the social economy of affairs that some of the oldest and most learned scientific associations, both in this country and in Europe, have been formed during the clash of arms and the din of war; and this Society is no exception. Nothing happens in this world by chance, though oftentimes it may be difficult to discover the law which underlies a principle.

The Massachusetts Medical Society was incorporated on November 1, 1781, and its charter was signed by Samuel Adams, as president of the Senate, and by John Hancock, as governor of the Commonwealth. These names suggest Revolutionary times and smack of patriotism. It will be noted that the centennial anniversary of the birth of the Society does not occur for some months to come; but it is fair to assume that the preliminary steps for its organization cover this interval. In the presence of this audience it need not be said that a period of gestation always precedes a birth; and without attempting to fix the limit of this period I shall assume that it is now a century since the conception of the Society took place in the brains of its founders.

There had been before this time a medical society in Boston, which was the first one formed in America. It appears to have been in existence as early as the year 1735, though it did not continue long. Its records are irretrievably lost, and all that is known about it is gathered from fragmentary sources. It is very likely that it included in its list of members some of the ministers, as they were interested in the study and practice of medicine. Dr. William Douglass,² a noted author and physician of that day, writes, under date of

February 17, 1735-36, to Cadwallader Colden, of New York, that, —

... "We have lately in Boston formed a medical society, of which, this gentleman [Dr. Clark, the bearer of the letter], a member thereof, can give you a particular account. We design from time to time to publish some short pieces; there is now ready for the press number one, with this title page: —

NUMBER ONE.

MEDICAL MEMOIRS

CONTAINING

- (1.) A miscellany. Practical introduction.
- (2.) A history of the dysentery epidemical in Boston in 1734.
- (3.) Some account of a gutta-serena in a young woman.
- (4.) The anatomical inspection of a spina ventosa in the vertebrae of the loins in a young man.
- (5.) Some practical comments or remarks on the writings of Dr. Thomas Sydenham.

Published by a Medical-Society in Boston, New-England."

This letter is now among the Colden Papers, in the possession of the New York Historical Society; a copy of it is printed in the second volume, fourth series, of the Massachusetts Historical Collections (pages 188, 189).

Gutta serena, Englished into drop serene, was the cause of Milton's blindness. The poet alludes to himself, when he says: —

"Eyes that roll in vain
To find thy piercing ray, and find no dawn;
So thick a drop serene hath quenched their orbs."

The disease was afterward known as amaurosis. Spina ventosa is an affection of the osseous system, — according to old notions, — in which the texture of the bone dilates, seemingly distended with air.

The first number of these Medical Memoirs was never printed. It was probably Dr. John Clark, at that time a prominent practitioner of medicine, who is referred to in the letter, as a member of the Society. He was born on December 15, 1698, and was then in the height of his professional zeal, when he would naturally be interested in a scientific association. He belonged to a family of medical antecedents and traditions, being himself of the fourth generation in a direct line of John Clarks, all physicians, and he was followed by three more, equally direct, of John Clarks, these three also physicians, — covering a period of more than a century and a half and including seven generations of the same name.

During the year 1736, Dr. Douglass published a pamphlet entitled *The Practical History of a New Epidemical Eruptive Miliary Fever, with an Angina Ulcusculosa which prevailed in Boston, New-England, in the years 1735 and 1736.* It is inscribed "To a Medical Society in Boston," and the preface begins: —

"Gentlemen, This Piece of Medical History does naturally address it self to you, considering that I have the pleasure of being one of your number, that you have been fellow labourers in the management of this distemper, and therefore competent judges of this performance, and that where difficult or extraordinary Cases have occurred in any of your private practice, I was favoured to visit the Patients in order to make a minute clinical enquiry:

¹ Through the courtesy of Dr. Green we are enabled to publish parts of his interesting Address at this early moment.

² Appendix A, p. 537.

in short, without your assistance, this piece would have been less perfect, and not so well couched."

In The Boston Weekly News-Letter, January 5, 1737, there is a long communication, addressed "To the Judicious and Learned President and Members of the Medical Society in Boston," and signed "*Philanthropos*." It takes strong ground in favor of regulating the practice of physic throughout the province, and advocates the plan of having all practitioners examined by a board of physicians and surgeons appointed by the General Court. The writer is justly severe on the "*Shoemakers, Weavers, and Almanack-makers*, with their virtuous Consorts, who have laid aside the proper Business of their Lives, to turn Quacks."

In the same newspaper of November 13, 1741, is an interesting report of a surgical operation performed about that time for urinary calculus, on Joseph Baker, a boy six years old. It was done "in Presence of the Medical Society," by Dr. Sylvester Gardiner, and "according to Mr. Cheselden's late Improvement of the lateral Way." The report begins:—

"A Medical Society in Boston New England, with no quackish View, as is the manner of some; but for the Comfort and Benefit of the unhappy and miserable Sufferers by excruciating Pain, occasioned by a Stone in the Bladder, do Publish the following Case."

Dr. Gardiner, the operator in this case, was a rising young surgeon who had studied his profession in London and Paris. He began the practice of medicine in Boston, where he also lectured on anatomy, which he illustrated by preparations brought from Europe. His enterprise led him to establish an apothecary's shop, in which he carried on an extensive wholesale and retail business. His career as a physician and surgeon was attended with remarkable success, and he soon acquired from his profession both fame and fortune. His prosperity, however, was interrupted by the political troubles which preceded the Revolution, and during the struggle he took sides with the mother country. He thus became odious to the patriots; and when Boston was evacuated by the British troops, he was compelled to leave his native country and pass eight or ten years in exile. He finally returned and died at Newport, Rhode Island, August 8, 1786, in the 80th year of his age.

Although the Medical Society in Boston was short-lived, no account of the history of medicine in the State would be complete which did not mention its existence. In its day it exerted a good influence on the profession, and showed a zeal on the part of the physicians which is alike honorable to their heads and creditable to their hearts. The origin of the Society may have had some connection with the epidemic of diphtheria which broke out in Boston during the summer of 1735; at any rate, it was organized about that time. It is known to have been in existence late in the autumn of 1741, though ten years afterward there was no trace of it. Dr. Lloyd, who began the practice of medicine in Boston about the year 1752, and continued in it for more than half a century, had no recollection of such an association. This fact is mentioned by Dr. Bartlett, in his address before the Massachusetts Medical Society, June 6, 1840, and shows that it had disappeared before Dr. Lloyd's time. The founders of this local society, the pioneer association of its kind in the country, represented the active medical thought in Boston; and, though they are unknown to us by name even, deserve on this occasion a tribute which is freely given.

A long generation passes, and the Massachusetts Medical Society takes the field, and occupies the broad limits of the State, including the District of Maine. Many of the original members had served in the army, and were familiar with the capital operations of the hospital and the battle-field, while others had filled important public positions of a civil character. In any prescience they would have been considered accomplished physicians and surgeons, and they were the peers of other professional men. Together with the clergy they represented the education and refinement of the community.

II. The rise and progress of medicine in Massachusetts during the colonial and provincial periods gives some idea of the antecedents and traditions of the Medical Society. The corner-stone was laid on such a ground-work; the structure was built on such a foundation. It was so planned that additions and changes might be made to meet the wants of advancing time, and not weaken the unity or symmetry of the whole. The workmen were earnest and honest, and the result proves their faithful labor. They have erected an edifice which has stood the test of a century, and now bids fair to last for ages to come.

I now purpose to trace in some detail the development of the Society from its beginning, one hundred years ago, to the present time.

Civil commotion stirs up thought and quickens mental activity. When the first steps were taken to establish this Society, the surrender of Yorktown had not occurred, and it was a matter of grave doubt when the Revolution would come to an end; but a six years' war had drilled the popular mind in great things. The uncertainty of public affairs tended rather to excite effort than to repress it. In such a time and under such conditions the Massachusetts Medical Society was organized. It was no small affair to bring together from all parts of the Commonwealth the representatives of the medical profession and to harmonize their conflicting views. Berkshire County was two days distant from Boston, and relatively as far off as Chicago and St. Louis are to-day; while that large northeast territory, called the District of Maine, was almost as little known as the farthest northwest region is known to us now. Between the different sections of the State there were then small conveniences for general travel and few postal facilities, by means of which an interchange of visits and ideas, so conducive to unification of action, could be brought about. The formation of this Society at once increased professional intercourse, in spite of these difficulties, and accomplished excellent results.¹

The act of incorporation, under which this Society first met one hundred years ago, is found in the first volume of its Communications, pp. 8-11, and is as follows:—

COMMONWEALTH of MASSACHUSETTS, in the year of our Lord, 1781. An Act to incorporate certain physicians, by the name of The Massachusetts Medical Society.

As health is essentially necessary to the happiness of society; and as its preservation or recovery is closely connected with the knowledge of the animal economy, and of the properties and effects of medicines; and as the benefit of medical institutions, formed

¹ Appendix B, p. 538.

on liberal principles, and encouraged by the patronage of the law, is universally acknowledged : —

Be it therefore enacted by the Senate and the House of Representatives in General Court assembled, and by the authority of the same, That Nathaniel Walker Appleton, William Baylies, Benjamin Curtis, Samuel Danforth, Aaron Dexter, Shirley Erving, John Frink, Joseph Gardner, Samuel Holten, Edward Augustus Holyoke, Ebenezer Hunt, Charles Jarvis, Thomas Kast, Giles Crouch Kellogg, John Lynn, James Lloyd, Joseph Orne, James Pecker, Oliver Prescott, Charles Pynchon, Isaac Rand, Isaac Rund, Jr., Micajah Sawyer, John Sprague, Charles Stockbridge, John Barnard Swett, Cotton Tufts, John Warren, Thomas Welsh, Joseph Whipple, William Whiting, be, and they hereby are, formed into, constituted and made a body politic and corporate, by the name of The Massachusetts Medical Society; and that they and their successors, and such other persons as shall be elected in the manner hereafter mentioned, shall be and continue a body politic and corporate by the same name forever.

And be it enacted by the authority aforesaid, That the Fellows of said Society may from time to time elect a president, vice-president, and secretary, with other officers as they shall judge necessary and convenient; and they, the Fellows of said Society, shall have full power and authority, from time to time, to determine and establish the names, number, and duty of their several officers, and the tenure or estate they shall respectively have in their offices; and also to authorize and empower their president or some other officer to administer such oaths to such officers as they, the fellows of said society, shall appoint and determine for the well ordering and good government of said Society, provided the same be not repugnant to the laws of this commonwealth.

And be it enacted by the authority aforesaid, That the Fellows of said Society shall have one common seal, and power to break, change, and renew the same at their pleasure.

And be it enacted by the authority aforesaid, That they, the Fellows of said Society, may sue and be sued in all actions, real, personal, or mixed, and prosecute and defend the same unto final judgment and execution, by the name of The Massachusetts Medical Society.

And be it enacted by the authority aforesaid, That the Fellows of said Society may from time to time elect such persons to be Fellows thereof, as they shall judge proper; and that they, the Fellows of said Society, shall have power to suspend, expel, or disfranchise any Fellows of said Society.

And be it enacted by the authority aforesaid, That the Fellows of said Society shall have full power and authority to make and enact such rules and bye laws for the better government of said Society, as are not repugnant to the laws of this Commonwealth; and to annex reasonable fines and penalties to the breach of them, not exceeding the sum of twenty pounds, to be sued for and recovered by said Society, and to their own use, in any court of record within this Commonwealth proper to try the same; and also to establish the time and manner of convening the Fellows of said Society; and also to determine the numbers of Fellows that shall be present to constitute a meeting of said Society; and also, that the number of said Society, who are inhabitants of this Commonwealth, shall not at one time be more than seventy, nor less than ten; and that their meetings shall be held in the town of Boston, or such other place within this Commonwealth, as a ma-

jority of the members present in a legal meeting shall judge most fit and convenient.

And whereas it is clearly of importance that a just discrimination should be made between such as are duly educated and properly qualified for the duties of their profession, and those who may ignorantly and wickedly administer medicine, whereby the health and lives of many valuable individuals may be endangered or perhaps lost to the community : —

Be it therefore enacted by the authority aforesaid, That the President and Fellows of said Society, or other such of their officers or Fellows as they shall appoint shall have full power and authority to examine all candidates for the practise of physic and surgery (who shall offer themselves for examination, respecting their skill in their profession), and if upon examination the said candidates shall be found skilled in their profession, and fitted for the practise of it, they shall receive the approbation of the Society in letters testimonial of such examination, under the seal of the said Society, signed by the President, or such other person or persons as shall be appointed for that purpose.

And be it further enacted by the authority aforesaid, That if the said president, and such other person or persons, so elected and appointed for the purpose of examining candidates as aforesaid, shall obstinately refuse to examine any candidate so offering himself for examination aforesaid, each and every such person so elected and appointed as aforesaid, shall be subject to a fine of *one hundred pounds*, to be recovered by the said candidate, and to his own use, in any court within this Commonwealth proper to try the same.

And be it further enacted by the authority aforesaid, That the Fellows of said Society may, and shall forever be deemed capable in law of having, holding, and taking in fee simple or any less estate, by gift, grant, or devise, or otherwise, any land, tenement, or other estate, real or personal; provided that the annual income of the whole real estate that may be given, granted, or devised to, or purchased by the said Society, shall not exceed the sum of *two hundred pounds*, and the annual income or interest of said personal estate, shall not exceed the sum of *six hundred pounds*; all the sums mentioned in this act to be valued in silver at *six shillings and eight pence* per ounce: And the annual income or interest of the said real and personal estate, together with the fines and penalties paid to said Society, or recovered by them, shall be appropriated to such purposes as are consistent with the end and design of the institution of said Society, and as the Fellows thereof shall determine.

And be it further enacted, That the first meeting of the said Medical Society shall be held in some convenient place in the town of *Boston*; and that *Edward Augustus Holyoke, Esq.* be, and he hereby is authorized and directed to fix the time for holding the said meeting, and to notify the same to the Fellows of said Medical Society.

IN THE HOUSE OF REPRESENTATIVES, *October 30, 1781.*

This bill having had three several readings, passed to be enacted. NATHANIEL GORHAM, *Speaker.*

IN SENATE, *November 1, 1781.*

This bill had two several readings, passed to be enacted. SAMUEL ADAMS, *President.*

Approved, JOHN HANCOCK.

A true copy.

Attest, JOHN AVERY, JR., *Secretary.*¹

¹ Appendix C., p. 533.

In accordance with the last clause of this Act, Dr Holyoke published a notice in *The Boston Gazette* and *The Country Journal*, November 12, 1781, calling a meeting of the members whose names are mentioned in the charter. It was called "at the County Court-House, in Boston, on Wednesday the 28th Day of this Instant November, at Ten o'Clock, A. M. for the Purpose of choosing Officers of the Society, and transacting any other Matter (which by this Act they are empowered to do) as they shall think proper."¹ The charter members were thirty-one in number, and represented different sections of the State: fourteen of them lived in Boston; two in Newburyport; two in Salem; and one in each of the following towns: Cambridge, Danvers, Dedham, Dighton, Great Barrington, Groton, Hadley, Northampton, Portland, Rutland, Scituate, Springfield, and Weymouth. By counties, as constituted at that time, Suffolk had sixteen members; Essex had five; Hampshire three; Middlesex two; Berkshire, Bristol, Plymouth, Worcester, and Cumberland, in the District of Maine, one each.

The first meeting of the corporation was duly held in the county court-house, on November 28, 1781, at which time there were present nineteen of the thirty-one persons whose names are given in the Act of Incorporation.² The court-house of that period stood on the site of the present one in Court Street. The first vote passed was that the officers at this meeting should be chosen *pro tempore*; and subsequently "Edward Augustus Holyoke Esq;" was elected president, "Doct^r. Isaac Rand jun^r," secretary, and "Doct^r. Thomas Welsh," treasurer. The records follow the precedent of the Act in withholding the medical title from Dr. Holyoke's name. Perhaps it was because Dr. Holyoke held a commission as justice of the peace, and the title of esquire at that time carried a great deal of dignity with it.

The second meeting was held in the court-house, on April 17, 1782, and Dr. Samuel Holten chosen president *pro tempore*.³ A committee, consisting of Drs. Tufts, Warren, and Appleton, was appointed to consider the form of letters testimonial to be given to those candidates who were approved by the Censors of the Society; and to invent a device and motto for a seal. This was an important committee, and they appear to have reported at the next meeting, — though I do not find any record of the details, — when they asked for further time in regard to the seal. One of the prime objects of the Society was to draw the line between the intelligent and the ignorant practitioners of medicine; and it was the function of this committee to devise some method to reach this end. Even the matter of the seal was considered sufficiently important to be mentioned in a separate clause of the original Act.

The third meeting was held on June 5, 1782, and Dr. James Lloyd chosen president "*pro hac vice*." At this meeting permanent officers were elected for the ensuing year; and as the pioneers of a long line of eminent physicians who have held office in this distinguished organization, I give the names of them all, as taken from the records: —

Edward Augustus Holyoke Esq., President
Doct^r James Pecker, Vice President

Doct ^r Samuel Danforth	}	Counsellors
Doct ^r Joseph Gardner		
Hon: Sam ^l Holten Esq.		
James Lloyd Esq.		
Doct ^r Isaac Rand jun ^r		
Doct ^r John Sprague	}	Corresponding Sec ^r
Hon: Cotton Tufts Esq.		
Doct ^r John-Barnard Swett		Recording Sec ^r
Doct ^r Nath-Walker Appleton		Treasurer
Doct ^r Thomas Welsh		Vice Treasurer & Librarian
Doct ^r Aaron Dexter		
Doct ^r Sam ^l Danforth	}	Censors
Doct ^r Charles Jarvis		
Doct ^r Joseph Orne		
Hon: Cotton Tufts Esq.		
Doct ^r John Warren		

At this meeting it was voted

"That a Committee be appointed to publish a List of the Officers this day elected, to announce to the Public that the Massachusetts Medical Society is organized, also to invite the Correspondence of the Faculty and others as they shall think proper."⁴

By the Act of Incorporation, Dr. Holyoke was empowered to name the time and place for holding the first meeting of the Society; and it was a fitting supplement to the previous arrangements that he should be chosen its first president.⁵

The fourth meeting of the Society was held on July 18, 1782, when "The Com:" appointed to agree upon a Device and Motto for a Seal, laid several Devices before the Society, particularly a Figure of Æsculapius in his proper habit pointing to a wounded Hart nipping the Herb proper for his Cure with this Motto '*vivere natura*.'" The design was adopted, though the motto was changed to *naturâ duce*; and the same committee was authorized to procure a seal made after this device.

The fifth meeting was held on September 4th, when it was voted, "That the Fellows of this Society be requested to transmit to the Recording Secretary an Account of those Diseases that have from one stated Meeting to another been most prevalent in the Circle of their practise, that the same may be laid before the Council for their inspection and such communicated to the Society as the Council shall direct." Many such papers were then sent in, which are now carefully preserved on the Society's files.

The sixth meeting was held on October 16th, but no quorum was present.

The seventh meeting was held on April 9, 1783, when the committee on the seal reported that they had procured one, which was laid before the Society and unanimously accepted. It was also voted that candidates for practice, who had passed a satisfactory examination by the Censors, should pay the sum of eight Spanish milled dollars. A circular letter was adopted to be sent to those members mentioned in the Act of Incorporation, who had not been present at any of the meetings. By the records it appears that there were eight such persons. The letter is as follows: —

"Sir, The Fellows of the Mass: Medical Society, who have met from time to time for the purposes of their appointment, have conceived themselves happy in your having been appointed one of its Fellows, and

Ed.

beg Leave to assure you, that your Communications will at all times be highly acceptable; and that they are sincerely desirous of your Assistance in carrying on the Business of the Society, which in its Beginning call for more particular Exertions, and requires the joint Efforts of all its members.

"The Society has been so unfortunate as not in any way to be informed of the Determination of several Gentlemen, appointed by an Act of the General Court Fellows thereof, relative to the Acceptance of the Trust, for want of which information, the Society in the prosecution of its Business, has found itself embarrassed and unable to make such arrangements as might more fully tend to promote the Ends and Designs of the Institution, for which Reason we have addressed you on the subject; not doubting of your benevolent Intentions and Readiness to promote an Undertaking, conducive as we hope to the Benefit of Mankind in general and the Medical Faculty in particular. We presume that your answer of acceptance will be forwarded by the first opportunity."

"With sentiments of Respect and Esteem,
"We are &c."

At the same meeting a Resolve was read, passed by the General Court March 20, on the petition of Cotton Tufts, granting the use of a room in the Manufactory House to the Massachusetts Medical Society, in connection with the American Academy of Arts and Sciences. The Manufactory House was a noted public building of that time, belonging to the State, and situated on Tremont Street, nearly opposite to the site of the Park Street Meeting-house. The room was fitted up conjointly by the two associations, and first used by the Medical Society on October 15, 1783. It was occupied by them for the stated meetings held on October 30, and April 14, 1784, and probably for other minor purposes. The meeting on June 2, as well as the one on June 21, took place in the county court-house, where all the former ones had been held, before the room in the Manufactory House was occupied. The meeting of April 13, 1785, was held in "the Stockholders' room in the Bank." The Massachusetts Bank, at that time the only one in the State, was organized in the year 1784, at which date it bought the Manufactory House, sold by order of the General Court. 'The stockholders' room in this building was the apartment previously used by the Society. The meeting of May 4, 1785, took place in the Senate Chamber of the Old State House, and the one of October 19, 1785, was held in "Mr. Furnass's painting room in Court St.;" while that of October 18, 1786, was "in the hired room in Court Street,"—which may have been the same as Mr. Furnass's room. The meetings of October 20, 1790, and April 13, 1791, were held in Concert Hall, a noted tavern at the southerly corner of Court and Hanover streets. I have been particular in giving some of the minor details of the early history of the Society, in order to show its small beginnings and the changing places of its meetings. It is well sometimes to compare present opportunities with the narrow means of past generations.

The birth of the present Medical School in the year 1783 formed an epoch in the medical history of the State, though the Massachusetts Medical Society, as a corporate body, did not officiate on the occasion. At first the school was looked upon by the Fellows with some jealousy, as they feared that the existence of

two institutions would lead to serious embarrassments. The matter was considered of sufficient importance to be referred to a special committee of the Society, which, however, did not report for nearly three years. At the meeting held on October 15, 1783, it is recorded that

"Upon a Recommendation of Council to consider Whether the Doings of any of the literary Societies in this Commonwealth, interfere with the Charter Rights of the Medical Society;

"Voted That a Com: of three be appointed to take into Consideration the above Recommendation and to confer with any such Societies (upon the Subject, as they may think proper) and report:

"Voted That Dr. Cotton Tufts, Dr. Kneeland & Dr. Appleton be this Committee."

Nothing further relating to this subject appears to have been done, until the meeting on June 7, 1786, when:—

"The Com: appointed on 15 Oct. 1783 to consider whether the Doings of any of the literary Societies in this Commonwealth interfere with the Charter Rights of this Society, & to confer with any such Societies upon the Subject as they might think proper, reported, That they had attended the Business of their appointment upon examining the Medical Institutions of Harvard College, the Com: were of opinion that those Institutions did interfere with the Charter Rights of this Society 'to examine Candidates for the practise of Physic & Surgery & to grant Letters testimonial of the Examination of such as shall be found skilled in their profession' in that, those Institutions provided for the Medical professors of that College examining their Pupils & granting Letters testimonial or public Certificates to such of them as they judged proper, of their Abilities to practise physic. Whereupon the Com: applied to the Government of the College for a Conference upon the Subject, which was had, & ended in an agreement that the Com: should confer with the Medical professors of the College & make such arrangements respecting this matter as should be mutually agreed upon for the Honor of both Societies & the advancement of Medical Knowledge. This Conference between those Medical professors & the Com: for some reasons, unknown to the Com: was never held. The Com: further report that it has lately been suggested to them that the Medical Institutions of Harvard College have been altered, whereupon Enquiry was made respecting the Matter and an Acc^o of the above Institutions authenticated by the Sec^y. of the Overseers, was procured, and upon a careful examination the Com: were clearly & unanimously of Opinion that Harvard College Medical Institutions do not and that no Doings of that or of any other literary Society do, as far as the Com: could find, interfere with the Charter Rights of this Society."

At this time there were but three professors in the Medical School; and two of these were original members of the Medical Society. It was, therefore, extremely improbable that there would be any permanent friction between the two bodies. The Medical Society had no right to confer degrees; and it does not appear that the Medical School had any intention of granting testimonial letters to the profession at large. What then bid fair to be a little tempest soon subsided.

At the meeting held October 26, 1785, corresponding and advising committees were appointed for the different counties of the State, in order to encourage

reports of professional cases to this Society; and many years later, on April 28, 1803, it was voted, —

"That the Commonwealth be divided into four Districts, the Middle, Southern, Eastern, and Western; the Middle to consist of Suffolk, Norfolk, Essex, and Middlesex; the Southern of Plymouth, Bristol, Barnstable, Dukes County, and Nantucket; the Eastern district [to consist] of Maine; the Western [of] Hampshire, Bristol, and Worcester."

Immediately afterward committees were appointed for each of these districts, "to ascertain who are deserving of becoming Fellows." These organizations have since grown and become the present District Societies.

At the meeting held on November 8, 1786, the council of the Society was requested to consider the propriety of addressing the legislature that some measures might be taken to prevent the sale of bad and adulterated medicines, and to report thereon.

In the spring of 1790, the first number of a publication entitled *Medical Papers* was prepared under the direction of the Society, and five hundred copies printed; but, for the want of funds, the second number did not appear until the year 1806. The third number was printed in 1808, which completed the first volume of the series now known as the *Medical Communications of the Massachusetts Medical Society*. It is made up almost entirely of papers written by the members, giving the result of their observations on diseases and epidemics in their respective neighborhoods. The address of Dr. Isaac Rand, delivered June 6, 1804, is usually bound in this volume. Its subject is *Observations on Phthisis Pulmonalis*; and it is the first one of the long series of annual addresses made before the Society. This pamphlet became so rare that, by a vote of the councilors, it was reprinted in the year 1853. It was published in exact *fac-simile*, under the careful supervision of our late associate member, Dr. Nathaniel Bradstreet Shurtleff. The *Medical Communications* have been continued until now, when they comprise a work of twelve volumes. One number of the *Communications* appears each year, and five or six of them make up a volume; the later numbers consisting of the annual addresses, proceedings of the meetings, and other papers.

A *Pharmacopœia*, prepared by Drs. James Jackson and John Collins Warren, was published in the year 1808, under the auspices of the Society. It was formed on the plan of the *Pharmacopœia* of the Edinburgh College, and was designed to introduce modern nomenclature, and to establish greater uniformity in the prescriptions of physicians. The *American New Dispensatory*, written by Dr. James Thacher, and published in the year 1819, was submitted to a committee of this Society, and received its official sanction. The basis of this work was the *Pharmacopœia* which has just been mentioned.

"The Publications of the Massachusetts Medical Society," technically so called, were begun in the year 1800, and kept up until 1871. They consist of three volumes, comprising, for the most part, essays and reports read at the meetings, and subsequently published. Papers of this character are now printed in the *Communications*, and do not appear in any separate serial.

It may not be inappropriate to mention in this place *The New-England Journal of Medicine and Surgery*, which was published quarterly in Boston. While it

was not an official organ, it was "conducted by a number of physicians," in the warmest interest of this Society. It was edited with much ability, and contained many original papers. It began in the year 1812, and was kept up until 1828, when it was followed by *The Boston Medical and Surgical Journal*, a publication which has continued till the present time.

The protective power of vaccination was discovered in England by Edward Jenner, near the end of the last century; and the news of its discovery was soon brought to this country. Among the first persons here and perhaps the first whose critical attention was called to its importance, was Dr. Benjamin Waterhouse, of Cambridge, an early Fellow of this Society. Its introduction, like that of variolous inoculation, was destined to meet with many difficulties and obstacles; and Dr. Waterhouse was to be the champion. He wrote much as an advocate of the cause; and against popular ridicule and prejudice he succeeded in carrying the day. A communication, signed with his initials and dated at Cambridge, March 12, is found in the *Columbian Centinel* of March 16, 1799. It is headed "*Something curious in the MEDICAL LINE*," and is the first account of vaccination that was given to the public in this country. In the article Dr. Waterhouse describes cow-pox, and says that it must not be confounded with another disorder incident to the human race, which bears a somewhat similar name. He printed the account in a newspaper in order to excite "the attention of our dairy farmers to such a distemper among their cows," and to inform the profession generally of this security against small-pox.

In the year 1800 he published a tract entitled "*A Prospect of exterminating the Small-Pox, being the history of the Variola Vaccina, or Kine-pox*" etc.; and in it he describes the method he used, July 8, 1800, in vaccinating his son, Daniel Oliver Waterhouse, a lad five years of age, who had this disease in a mild way. From the arm of this boy he vaccinated another son, three years old, who had the customary symptoms in a light form; and subsequently he "inoculated a servant boy of about twelve years of age, with some of the infected thread from England." This expression furnishes the clew to the method adopted for obtaining the vaccine virus, which came "by a short passage from Bristol, England; though in the autumn of 1802, Dr. Waterhouse speaks of receiving quill-points, or "tooth picks," charged with virus. Before he had finished the practice in his own family, he had vaccinated four of his children and three of his servants, with no serious symptoms or consequences. The faith he had in the efficacy of the operation, prompting him to try it on one of his own children, was of that living kind which always commands attention. In this matter we are reminded of Dr. Boylston's bold act in inoculating his son for small-pox.

In the year 1802 Dr. Waterhouse published a work of 134 pages, which formed Part II. of the previously-mentioned tract; and in it he gives a full account of the new inoculation in America. In all his efforts to introduce vaccination, Dr. Waterhouse was warmly seconded by Dr. William Aspinwall, of Brookline, who deserves no small meed of praise in this matter. Dr. Aspinwall had paid much attention to variolous inoculation; and after the death of Dr. Boylston, the first American inoculator in point of time, he erected small-pox hospitals in Brookline, where he treated a large number of patients for the disease, which had been ar-

tificially induced. No man in America, probably, ever inoculated so many persons, or enjoyed so wide a reputation for his skill in so doing, as Dr. Aspinwall.

Massachusetts was the first colony to introduce small-pox inoculation, and she was also the first State to adopt kine-pox vaccination; and her towns have always taken the lead in sanitary matters. During the summer and autumn of 1802 some interesting experiments were conducted under the direction of the Boston Board of Health, whose unremitting exertions at that time, to prevent contagious diseases, entitle them to the highest praise. The Board fitted up a hospital on Noddle's Island, now known as East Boston, and invited a number of physicians to coöperate with them in an undertaking to diffuse knowledge and dispel prejudice in regard to vaccination. Some bold experiments were tried at this hospital, and fortunately all were highly successful. On August 16th, nineteen boys were vaccinated; and all passed through the regular stages of the cow-pox: and on November 9th, twelve of these children, together with a son of Dr. Bartlett, who had previously had the cow-pox, were inoculated for the small-pox, with matter taken from a patient in the most infectious state of the disease, and no trouble whatever followed. In order to show the true variolous character of the virus used in this experiment, two lads were inoculated at the same time with the same matter; and in due time a severe eruptive fever followed, with a plentiful crop of variolous pustules. When these two cases were in the right stage, matter was taken from them and inserted, for the second time, in the arms of the twelve children who had been previously inoculated, and besides in the arms of the other seven boys who were absent at the first inoculation. They had, moreover, been exposed to infection, most of them for twenty days, by being in the same room with the two lads who had the small-pox; and all nineteen escaped. These and other facts are given in a report which was made and signed by eleven physicians,—James Lloyd and Benjamin Waterhouse appearing at the head of the list. A full and official account of the whole affair is found in the *Columbian Centinel*, December 18, 1802.

The town of Milton was the first to act in its corporate capacity, and extend the benefits of vaccination to its citizens. In the year 1809, three hundred and thirty-seven persons of different ages and conditions among its inhabitants were vaccinated; twelve of them were afterward tested by inoculation for small-pox, and found fully protected. The test was conducted by Dr. Amos Holbrook, a Fellow of this Society; and the twelve persons—eight boys and four girls—were volunteers for the operation. The town acted during the whole affair in a most liberal and intelligent spirit, and published a valuable pamphlet, setting forth all the transactions concerning it. It was entitled "A Collection of Papers relative to the Transactions of the Town of Milton, in the State of Massachusetts, to promote a General Inoculation of the Cow Pox, or Kine Pox, as a never failing preventive against Small Pox Infection"; and a copy was sent to the selectmen of each town in the Commonwealth.

About this time a similar plan of public vaccination was adopted at New Bedford. By an act of the General Court, passed March 6, 1810, the towns throughout the State were directed to appoint committees to superintend the matter, and authorized to defray the expenses of a general system of vaccination. The

motive power of all these proceedings was furnished by the Massachusetts Medical Society, though it was not always apparent.

By the act of incorporation the membership of the Society was limited to seventy persons; but on March 8, 1803, an additional act was passed by the General Court, which removed all limitation and made many changes in other respects. Since then the number of fellows has been steadily increasing; and at the present time every town in the State, with the exception of a few small ones, is represented among the members.

In the winter of 1811, an effort was made to obtain from the General Court a charter for another medical society, to be called the Massachusetts College of Physicians. The movement was strenuously opposed, as might have been expected, by the Massachusetts Medical Society; and a long controversy was the result. There had not been so much personal and professional feeling excited among the physicians of the State, since the introduction of small-pox inoculation, ninety years before this time.

The following petition to the legislature was received by that body on February 12, 1811, and referred by them six days afterwards to the next General Court:—

"To the Honourable the Senate, and the Honourable the House of Representatives, in General Court assembled, this petition most respectfully sheweth:—

"That seeing health is a blessing, which sweetens all our enjoyments; and long life that which all men naturally desire, so everything that tendeth to secure the one or leadeth to the other, is an object worthy the attention of this legislature.

"And considering, moreover, that of the various methods of obtaining and diffusing medical knowledge, not one is found so effectual and desirable as a friendly and liberal intercourse and honorable associations of its professors; more especially when their end and aim is mutual improvement and the publick good; and experience has proved that two literary and scientific societies produce more than double the advantage of one—

"Influenced by these sentiments, we your petitioners humbly pray the Honourable the Legislature to constitute us, and such may hereafter associate with us, a body politic and corporate, by the name and title of the Massachusetts College of Physicians; with such powers, privileges and immunities, as other medical associations of the like nature and views enjoy, under the same denomination, in several states of the union.

"And your petitioners shall, as in duty bound, ever pray.

THOMAS WILLIAMS.	JAMES MANN.
SAMUEL DANFORTH.	CHARLES WINSHIP.
MARSHALL SPRING.	ABRAHAM DRAPER.
NATH. AMES.	JAMES LOVELL.
WILLIAM ASPINWALL.	JACOB GATES.
JOHN JEFFRIES.	WILLIAM INGALLS."

At the annual meeting of the Medical Society, held June 5, 1811, a committee, which had been appointed "to prepare a memorial to the General Court respecting a petition for the incorporation of a college of physicians," presented the following remonstrance. It was adopted almost unanimously, one member only out of seventy-two dissenting:—

"To the Honourable the Senate and the House of Representatives of the Commonwealth of Massachusetts.

"The Massachusetts Medical Society, in consequence of an application to the General Court in February last, for the incorporation of a College of Physicians, beg leave respectfully to represent.—

"That the said Massachusetts Medical Society was established in November, 1771, with power to elect officers, examine and licence candidates for practice, hold estate, and perpetuate its existence as a body corporate. In June, 1782, the Society was organized agreeably to the provisions of the statute, and the members directed in every way to extend and increase its usefulness. By an additional act of the General Court in February, 1789, authority was given to point out and describe such a mode of medical instruction as might be deemed requisite for candidates previous to examination; which important duty has been constantly attended to, and occasionally revised. By a further additional act in March, 1803, as the Society was thought too limited to answer the purposes of its establishment, its state was so essentially changed that the number of its Fellows originally limited to seventy, may embrace all respectable physicians and surgeons resident in the State; and that district societies may be established in such places as will facilitate medical improvement, and prevent the inconvenience of applying in all cases to the censors in Boston for an examination.

"In consequence of this provision, several district societies are formed, and are in a prosperous condition, cultivating medical science, and qualifying candidates, in various parts of the Commonwealth. It has been the constant endeavour of the Society, without reference to local or political considerations, to admit the most respectable practitioners in every section of the State, and they are desirous to elect all others of known talents who, by accident or from any other cause, are not admitted.

"The number of candidates licensed for practice by the Society is more than eighty, all of whom, as well as all bachelors of medicine in Harvard University, may claim admission as Fellows of the Society, after three years' practice.

"The present number of Fellows exceeds two hundred. Publications of important cases communicated to the Society; of a Pharmacopœia, which is now in general use; and of Dissertations read at the meetings, have been made, as often as the funds would possibly admit; committees have been appointed to investigate the nature, causes, and cure of epidemics, and the result of their inquiries communicated to the publick. The greatest harmony has distinguished their proceedings. No mention was ever made, as has been insinuated, of regulating fees in practice. The sole object of the Society has been to promote the design of its institution and the Fellows have been led to believe by the constant patronage and support of the Legislature, as well as the publick voice, that their conduct has been approved.

"It is scarcely necessary to remark, that, from the state of medical science, at the incorporation of the Society, its progress, for several years, was slow, and that it was less useful than could have been wished; but by the aid and cooperation of the flourishing medical school at the University, it is at this time in a most prosperous state; and it is the united endeavour of all

to promote medical instruction, and discourage unworthy practices.

"It is found on examination that the petition on the files of the General Court, for a College of Physicians, is for similar powers and privileges with this Society, on the ground, 'that two literary and scientific societies would produce more than double the advantages of one.'—The Society presume not to dictate to the Legislature on this important subject; but they beg leave respectfully to offer an opinion, that the establishment of such an institution can effect no object, not accomplished by existing societies, and would be so far from promoting a laudable and useful emulation, that candidates rejected by one society would resort to the other, with the greatest hopes of success, whatever might be their qualifications for the proper exercise of their profession. Hence would arise disagreements and animosities, which in other parts of the United States (particularly in Philadelphia at a former period, and very recently at New York) have been injurious to the profession and to the publick. Such animosities were threatened in the infancy of this establishment, by a supposed interference of Harvard College with the rights of the Society, and would have produced the most unhappy effects, but for the repeal of an exceptionable article in that establishment, and the accommodating conduct of those who at that period were the guardians of science, and the patrons of the healing art.

"From these considerations, and from other circumstances which the Medical Society are prepared to state, they have thought it an incumbent duty to request that the prayer of the said petition should not be granted, and they as in duty bound will ever pray.

"In behalf of the Society,

"JOHN WARREN, *President.*

"BOSTON, June 5, 1811."

On June 11, 1811, both the petition and remonstrance were presented at the same time to the legislature; and they were referred to a joint committee of the House and Senate. After certain formalities final action was deferred until the second session of the General Court, which was to meet on January 8, 1812. During this interval communications appeared in the newspapers, and pamphlets were printed, setting forth the views of the writers on each side of the question. At one time it seemed as if the petitioners would be successful in their efforts, but finally they were defeated.

The speech of Governor Gerry, at the opening of the session, contained the following remarks:—

"Many Institutions in this Commonwealth which have promised great benefit to the public, would have met with much more success had similar Corporations been established. When only one of any kind is permitted, it too frequently happens that a majority of individuals composing it indulge their private views and interests, to the exclusion of men of the most enlarged, liberal, and informed minds, and thus destroy the reputation and usefulness of the society itself. The multiplication of such institutions has a tendency, not only to prevent this evil, which is an *opiate to genius*, but to produce a competition, and to promote in the highest degree the utility of such establishments."—*Columbian Centinel*, January 15, 1812.

An attempt had been made, before the legislature met, to mingle politics with the question and render it a party one; and it will be seen that the Governor threw his influence on the side of the petitioners.

In the early part of February, 1812, the committee of the legislature gave a hearing in regard to the matter in the Senate Chamber, which was filled at the time with spectators. Drs. James Mann, William Ingalls, Abijah Draper, and Joseph Lovell appeared in order to support the petition; and Drs. David Townsend, John Warren, Thomas Welsh, Aaron Dexter, Josiah Bartlett, William Spooner, and Benjamin Shurtleff, as a committee of the Medical Society, to defend the remonstrance. The petition was also advocated by Dr. Benjamin Waterhouse, Professor of Theory and Practice of Physic, who, with Drs. Leonard Jarvis, Edward Whitaker, Daniel Thurber, and Nathaniel S. Prentiss, had added their names to the subscribers. This brought out a reply from Dr. James Jackson, Professor of Theory and Practice, in behalf of the medical institution at Cambridge, as it was generally understood that a new medical school would be connected with the proposed establishment.

On the next day the committee reported, by a bare majority, so far in favor of the petitioners that they should have leave to bring in a bill, which report was accepted in the Senate. The proceedings of the House on February 13, 1812, in regard to it are found in the *Columbian Centinel*, February 15, and are as follows:—

"The report of a joint committee which had given leave for the introduction of a bill to incorporate a College of Physicians, and which report had been accepted in the Senate, was taken up in the House yesterday, when the House non concurred the vote of the Senate; and refused leave to bring in a bill.

"This day, Mr. Cannon moved to reconsider the vote of yesterday. This motion, which involved all the merits of the question, was advocated by the mover, Messrs. Martin of Marblehead, Austin of Charlestown, Green of Berwick, and others; and opposed by Messrs. Childs of Pittsfield, Mr. Kittridge, Messrs. Foster, Fay, Russell, Davis, and others, and was negatived. For it, 195; against, 211. The debate on this subject was animated and interesting, and lasted three hours. The gentlemen of the committee which reported the leave stated, that in the examinations before them, they found nothing to support nor justify the numerous insinuations and reports which had been circulated in print and in out-door conversation, tending to implicate and injure the existing Medical Society; but that the Society has stood, and now stands, on high ground for usefulness, impartiality, and respectability. It was clearly demonstrated—though attempts were made out doors to make it a party question—that the institution asked for is unnecessary, and that if granted would produce great dissensions among the faculty, and be highly injurious to the community."

Thus happily ended one of those unpleasant controversies which never lead to good results. The petition for the Massachusetts College of Physicians, as well as the remonstrance against it, are found in Dr. Bartlett's address delivered at the annual meeting of this Society, June 6, 1810, which was published "with alterations and additions to January 1, 1813," in the first volume, second series, of the Massachusetts Historical Collections. This edition of the address contains ten pages of matter more than the one printed in the second volume of the Medical Communications.

The Massachusetts Medical Society is now the oldest state organization in the country, of a similar character,

that has held its meetings continuously and regularly from the date of its incorporation. Since its foundation it has borne on its rolls the names of 3,700 persons; and to-day its membership includes 1,350 physicians from all parts of the Commonwealth. These members represent every section of the State, and their influence on one another is as immense as it is incalculable. The average attendance at the annual meetings of late years is not far from 750 members; these meetings last through two days, and with few exceptions have been held in Boston.

The charter of the New Jersey Medical Society antedates that of this Society by some years, but there have been breaks in its regular line of descent. During the Revolution there was a suspension of its meetings from the year 1775 to 1781, which was due to the interruption of the war; and then again from the year 1795 to 1807, this time owing to a general anæmic condition of interest, on the part of its members.

We now stand on the dividing line between two centuries, and we can look forward only so far as the light of the past illumines the vision. We see enough, however, to know that new ideas in the profession will be established, and new methods adopted. The physician of the coming period will have a broader knowledge of preventive medicine. The laws of infection and contagion will be better known, and the daily conditions of health and disease more thoroughly understood. The subtle connection between cause and effect will be more accurately defined; and what is now obscure will be made clear. The great fact is to be emphasized that everything in this life is related to what has gone before, and that we are what we are in consequence of antecedent circumstances. We may approach even to the curtain which nature drops over all vital action, but there we must stop; though in other directions the finger of Discovery points down endless paths. Yet with all the knowledge that the human intellect can master, the great problem of living organism will be as far from solution as it is to-day. Groping in the dark in respect to first causes, we must confess that life is an impenetrable mystery, and something more than chemical action, and something beyond protoplasmic development. For our purpose it is enough to know that the science of medicine will continue to the last point of measured duration; and, like a planet plunging on through the immensity of space, in its untiring and unending course, it will shed its rays of light and consolation wherever the atoms of humanity are found.

LETTER FROM DR. WIL. DOUGLASS TO THE ASSESSORS OF BOSTON, ASKING AN ABATEMENT OF HIS TAX, 1747.¹

APPENDIX A.

THURSDAY, April 23^d. 1747.

GENTLEMEN ASSESSORS OF THE TOWN OF BOSTON.

I am sorry for the necessity of giving you trouble from time to time of my complaints as being aggrieved in my Rate bills: last year you abated me sixty six pound old Tenor: which tho not a sufficient abatement, that I might ease you of the trouble of further application I acquiesced with the same.

The true, just and legal reasons of my complaint you may gather from the annexed Schedule of my

¹ The original is in the possession of Dr. John T. H. Fogg.

Estate. Further I may observe to you that I am or Soon must be in the Decline of Human life: therefore do not endeavor to increase my Fortune, having no family to provide for: but shall yearly lessen it, by doing charities in my life time by donations and bounties. This year I have Sold my garden in Atkinson Street to Mr. Thos: Goldthwait, and some lands in the country to several towards settling five hundred pounds O. T. upon a free school in Douglass, formerly New Sherburn, and of Fifty pounds p^r an. for the first seven years to their Minister, besides several other bounties to particular families. I contract the business of my Profession, because considering long outstanding debts and bad pay, it is an affair of more labour than profit.

If not relieved I can not be blamed, in applying further to the Quarter Sessions as the Law directs: where upon producing your Books, I shall make it appear that I am assessed more than my proportion with others (which the Law expressly calls a grievance) by comparing with some of the Assessors, with some of my own profession, and with some Merchant and Shop-keepers in Boston.

I have not inserted my Books and Instruments because they are the Tools of my Profession. I have not inserted my wearing apparel or furniture of two Rooms, as being of little value. I have no Plate, no Equipage. There is no legal Tax upon a man as a Bachelor, and for frugality in every thing excepting charities and an almost continued employ of tradesmen and labourers.

WIL. DOUGLASS.

Dr. Bulfinch who has by much the best business of the profession in Boston is assessed only 45£ O. T.

Dr. Kennedy I. Perkins & Sprague who follow more business than I do are assessed only 25£ to 35£ O. T.

Left it may appear invidious I shall not mention the proportional under-rates of some Merchant and tradesmen.

Mr. Clark the Hatter deceased worth 30,000£ to 40,000£ O. T. Estate was rated 38£ O. T.

Deacon Parker the Top Mason in Town full employed, 11£ O. T.

A schedule of the income of the real estate and of the personal Estate and faculty of Dr. Wil. Douglass for 1796 Real Estate under his own Improvement. Two chambers in Green Dragon value 35£ p^rann. O. T.

Personal Estate, viz.:

Income of real Estate. Old Tenor.

Green Dragon (the above 35£ O. T. is deducted) p^ran. £ 165 0 0

Jarvis in Roxbury and appurtenances. 100 2 0

Widdow Stoddard. 100 0 0

Pitson: half of late Capt Steels 60 0 0

Fowle: late Walkers near Orange. 50 0 0

House Mill-creek lane, Sundry Tenants. 50 0 0

Barnet: late Capt: Steels. 35 0 0

Major Sewall: a warehouse late Capt: Steels. 20 0 0

Money at Interest not exceeding 3 0 0

Income by faculty not exceeding 5 0 0

A Borne Negro boy purchased some time since for £ 17 12 O. T. 1 0 0 0

My outstanding Debts in Practice I will make over to any man for 1,000 0 0
My running Cash to defray incident charge, variable at a medium 100 0 0

Old Tenor. 2,615 2 0

BOSTON, April 21, 1747.

Suffolk Js.

Doct^r. William Douglass personally appeared & made solemn Oath that the above Schedule is a just & True estimate of the Income of his Real Estate, & of the Personal Estate & Faculty of him the said William, the whole amounting to two Thousand six hundred & fifteen Pounds two shillings old Tenor.

DOCUMENTS RELATING TO THE FOUNDATION OF THE MASSACHUSETTS MEDICAL SOCIETY.

APPENDIX B.

LETTER TO E. A. HOLYOKE FROM N. W. APPLETON.

BOSTON, Sept. 19, 1781.

HON^d. SIR,—The long intended Medical Bill has at last passed the two Houses & ordered to be engrossed. I understand Mr. Lowell has given you the outlines of it. I shall inclose you a list of the members & a few particulars respecting it. This will be handed you by my Parents, who are just setting out for a short Visit to Salem. I hope that whenever the first Meeting of the Society shall be appointed we shall have the Pleasure of your Company. With best Regards to the Family, I remain your obliged Friend & Servt.,

N. W. APPLETON.

A LIST OF THE MEMBERS OF THE MASSACHUSETTS MEDICAL SOCIETY AS ALPHABETICALLY ARRANGED IN THE ACT.

A. Appleton.	S. Prescott of Groton.
H. Baylies of Taunton.	S. Pyncheon of Springfield.
p. Curtis.	S. Rand, Sen., Cambridge.
p. Danforth.	p. Rand, Jr.
p. Dexter.	S. Sawyer Newbury Port.
p. Erving.	H. Sprague, Sen., Dedham.
H. Frink of the County of Worcester.	S. C. Stockbridge of Plymouth Co.
p. Gardner.	S. Swett of Newburyport.
S. Holden of Danvers.	S. Tufts of Weymouth.
S. Holyoke of Salem.	p. Warren.
S. Hunt of Northampton.	p. Wells.
p. Jarvis.	p. Whipple.
p. Kaff.	H. Whiting of Concord.
H. Kellog of Hadley.	
p. Linn.	
p. Lloyd.	
S. Orne of Salem.	
p. Pecker.	

Those with a p. fixed before the Name are the Petitioners. Those with an S. were nominated by the Society. Those with an H. were put on by the House of Representatives. Those with no Town after their Names are of Boston.

No fine of the Society is to exceed £20.

The sum to be recovered by a Candidate in Case the examining Committee refuse to examine, £100.

The Annual of the real Estate not to exceed £200.
The Annual of the personal Estate not to exceed £600.

APPENDIX C.

TO E. A. HOLYOKE.

BOSTON, October 31, 1781.

HON. SIR,—I am very happy in the Pleasure of informing you that the General Court have this day enacted the Medical Bill, & have appointed you to call the first Meeting; it is sent up to the Governor for his approbation, which no doubt will be given. The Gentlemen in the Town are desirous of having a Meeting as soon after you have received official Information as can be with convenience, previous to the setting in of Winter. This Appointment gives me Pleasure on several Accounts, one is that I hope thereby to have the Pleasure of seeing you in Town & I shall depend upon the Happiness of your Company to dine with me on the day you shall fix for your first Meeting. I think at present that the County Court House would be a good place; we can, doubtless, have a fire in the lobby (in case the court is not setting) which will be large enough to accommodate as many as will probably be at the Meeting. I remain, with Respect Your obliged Servt,

N. W. APPLETON.

APPENDIX E.

MINUTES OF THE FIRST MEETING OF THE MEDICAL SOCIETY.

At a Meeting of the Massachusetts Medical Society, agreeably to a Notification of Edward Augustus Holyoke, Esq. (for the original see the Files), at Boston, November 28th, 1781—

Present, Doctrs Appleton, Baylies, Curtis, Danforth, Gardner, Holyoke, Hunt, Jarvis, Kaft, Linn, Lloyd, Pecker, Rand, Rand junr, Sprague, Tufts, Warren, Welsh, and Whipple.

Voted, That the officers to be chosen at this meeting be *pro tempore*.

Voted, That a President, Secretary and Treasurer be chosen by Ballot.

Voted, That Scrutineers be chosen for the purpose of counting the Ballots.

Voted, That the number be three and Doctrs Sprague, Jarvis, and Rand Sr. be Scrutineers.

Voted, That a majority of the members present is necessary to constitute a choice. Upon the Ballots being taken, it appeared that the following gentlemen were chosen: Edward Augustus Holyoke Esq. President Doctr Isaac Rand Junr Secretary Doctrs Thomas Welsh Treasurer.

Voted, That a Committee be chosen to form a Code of Laws for the future Regulation of this Society, and make report at the next Adjournment.

Voted, That this Committee consist of seven. Viz. Doctrs Tufts, Lloyd, Holyoke, Warren, Danforth Rand Junr and Jarvis.

Voted, That the Secretary be directed and hereby is directed to procure three hundred Copies of the Charter, printed, for the Use of the Society.

Voted, That the Committee appointed to form a Code of Laws and be empowered to call a Meeting of this Society thro' the Secretary when they are ready to report.

APPENDIX G.

LETTER TO THE PUBLIC UPON THE INSTITUTION OF THE MEDICAL SOCIETY.¹

The design of the above Institution is to promote medical and surgical knowledge, Inquiries into the Animal Economy, and the Properties and Effects of Medicines, by encouraging a free intercourse with the Gentlemen of the Faculty throughout the United States of America, and a friendly correspondence with the eminent in those Professions throughout the World, as well as to make a just discrimination between such as are duly educated and properly qualified for the Duties thereof, and those who may ignorantly and wickedly administer Medicines, whereby the Health and Lives of many valuable Individuals may be endangered, and perhaps lost to the Community.

In so laudable and useful an Intention the Massachusetts Medical Society feel the most solid Encouragement in calling upon the wife and observant of the Faculty and upon the curious in every Profession, to communicate whatever may appear to them conducive to this great undertaking. They would wish that the most trifling Observations, if pertinent, may not be withheld.

Every communication will be gratefully received and treated with the utmost Candour.

For the Purpose of enabling the People at large (who might otherwise be incapable of properly discerning the Qualifications of Candidates for Practice) to distinguish the Persons upon whom they may rely, they have upon the principles of their Charter, appointed five Censors, whose Duty as assigned them is, to examine all Candidates for the Practice of Physic, and Surgery, who shall offer themselves, therefor, and to give Letters, testimonial of their Approbation, to those whom they shall find worthy of public Confidence. Such gentlemen as would present themselves Candidates for Examination will be seasonably notified of the stated meetings of the Censors in the weekly News-Papers of the Town of Boston.

APPENDIX H.

DRAFT FOR A LETTER FROM DR. HOLYOKE.

SALEM Oct. 3^d, 1768.

SIR,—I rec^d a Line by your son, desiring to be inform^d of the Terms upon which I should be willing to

&^d by a Line just rec^d by your son you Desire to be inform^d of y^e Terms upon w^{ch} I should be willing to Undertake Instructing him in y^e Study & Practice of Physick. To which I would answer £20. Ster^l a Year. to be paid annually.

That he Bed & Board at my House, & live conformable to y^e Rules & Orders of my Family.

That He attend upon & prepare Medicines for the Shop.

That He attend the Sick & Wounded under my Care.

That He write in & Post my Books of Account.

Collect Money, in short attend.

On my Part I promise to give Your son advice & Instructions, according to y^e best of my Capacity & Opport^y in the Theory & Practice of Physick Surgery & Pharmacy.

¹ Original in handwriting of Dr. John Warren.

APPENDIX D.

FAC-SIMILE OF DR. HOLYOKE'S SUMMONS FOR THE FIRST MEETING.

Salem Nov^r. 9th 1881

Whereas the General Assembly of this Commonwealth, hath by an Act passed ^{the last Session} ~~this present Session~~, incorporated the several Gentlemen whose Names are as follow Viz^t: Nathaniel Walther Appleton, William Baylies, Benjamin Curtis, Samuel Danforth, Aaron Dexter, Shirley Ensign, John Frink, Joseph Gardner, Samuel Holden, Edward Augustus Holyoke, Ebenezer Hunt, Charles Jarvis, Thomas Keft, Giles Crouch Kellogg, John Linn, James Lloyd, Joseph Orr, James Peck, Oliver Prescott, Charles Pyrchon, Isaac Rand, ~~Isaac Rand jun~~, Micajah Sawyer, John Sprague senior, Charles Stockbridge, John Benedict Sweet, Cotton Tufts, John Warren, Thomas Welch, Joseph Whipple, William Whiting, into a Body politic & corporate by the Name of the MASSACHUSETTS MEDICAL SOCIETY — and hath by said Act empowered the Fellows of said Society to choose a President, Vice-President, & Secretary, with other Officers as they shall judge necessary & convenient &c — and hath empowered said Fellows to have a common Seal &c — hath empowered them to sue & be sued — to Elect, suspend & expell Fellows of the Society — to make Rules & bye Laws, & to annex reasonable Penalties & Fines for the breach of them, not exceeding the Sum of £20. — to establish the Time & Manner of choosing the Fellows, & also to determine the Number of Fellows that shall constitute a Meeting of the Society — and hath also enacted that the Number of said Society who are Inhabitants of this Commonwealth shall not at any one Time ~~exceed~~ be more than 70, nor less than 20. — and that their Meetings be held at Boston or such other Place as the Majority shall judge fit — that the President & Fellows, or such others as they shall appoint shall have Power to examine all Candidates for the Practice of Physic & Surgery, who shall offer themselves for Examination, & shall give Letter testimonial of their Approbation under their Seal &c —

and if the Persons appointed to examine, obstinately refuse, they are subjected to a Fine of £100. — This Act also empowers the Fellows of said Society to hold & take in Fee Simple or any Land, Tenements or other Estate real or personal; provided the annual Income of the real do not exceed £200, & the annual Income of the personal do not exceed £600 — it is also thereby further enacted that the first Meeting of the Society be held in some convenient Place in the Town of Boston, & that Edward- Augustus Holyoke Esq. be authorized & directed to fix the Time for holding said Meeting, and notify the same to the Fellows.

1. and hath granted to said Society, their Powers & Immunities ~~as~~ by said Act may appear, &

In Pursuance therefore of the above Direction, I do hereby notify the Fellows of the Massachusetts Medical Society, whose Names are mentioned in ^{the} Act as above recited, to Meet at the County Court-House, in Boston, on Wednesday the 28th Day of this Instant November at 10 o'clock A.M. for the Purpose of Choosing Officers of the Society, & transacting any other Matter, (which by this Act they are empowered to do,) as they shall think proper.

E. A. Holyoke.

APPENDIX F.

FAC-SIMILE OF A LETTER FROM DR. HOLYOKE DECLINING A NOMINATION TO THE
PRESIDENCY.

Doct. Isaac Rand Junr?

Secretary
to the Massachusetts Medical Society
Boston.

To be communicated.

To the Massachusetts Medical Society

Gentlemen

I am highly obliged by that favourable Opinion which led you to confer such an Honour upon me, as that of President of the Medical Society — but as I feel myself so indifferently qualified to fill that Office, with the Dignity becoming it; — and as by the remoteness of my situation from the Capital, I shall not be able to attend the Meetings of the Society; I should be wanting in what I owe to myself, as well as in my Duty to the Society, if I did not waive the Acceptance of that Office, and with Gratitude for the Honour already done me, beg you to vote for some more proper Person to fill the Chair, as it is impossible for me to accept it.

I am Gentlemen Your much obliged

Salem April 15.
1882.

Your very humble Servant

E. A. Holyoke

FAC-SIMILE OF TWO PAGES FROM DR. HOLYOKE'S DAY BOOKS, 1750-1828. WITH EXPLANATIONS.¹

[illegible]

¹ The professional account books of Dr. Holyoke in the possession of the Essex Institute comprise 123 vols. of 90 pages each, and on each page is the entry of 30 visits, making on the average 12 visits daily for 75 years. Historical Collections of the Essex Institute, vol. xv. They bear date from 1749 to February, 1829. En.

2 Capt. John Crowninshield was the son of Dr. John Caspar Richter von Cronenshilt, German physician, who came to Boston from Leipsic about 1688. He came to Salem and was a successful merchant.

³ Jonathan Phelps, blacksmith, m., 1729, Judith Cox: their second daughter, Rachel, m. Daniel Hathorne, of Salem, and these were the grandparents of Nathaniel Hawthorne.

⁴ Capt. Nathaniel Andrew, of Salem, mariner and merchant, m. Mary, daughter of Nathaniel Higginson, a lineal descendant of Rev. Francis Higginson; their son, John, was grandfather of John A. Andrew, governor of Massachusetts 1861-66.

5. Madam Turner and family. She was the widow of Major John Turner, a noted merchant of Salem, long of the provincial council; b. 1671, m. Mary Kitchin 1701. Their son, John Turner, m. Mary Osborn, of Boston, 1738, whose daughter, Mary, m. Daniel Sargent, from whom sprang Lucius Manlius Sargent and descendants, of Boston.

The Kitchens and Turners were prominent families in Salem during the provincial period. H. W.

Medical and Surgical Journal.

WEDNESDAY, JUNE 9, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

THE JOURNAL'S COMPLIMENTS AND GOOD WISHES TO THE SOCIETY.

THROUGH the appreciative encouragement of the committee of arrangements of the Society, and by advancing one day its regular publication, the JOURNAL is able to dedicate to the Massachusetts Medical Society the present number, which the editors hope will not be found altogether unworthy, either in matter or form, of the centennial anniversary of the oldest surviving medical society in this country. The JOURNAL is glad to avail itself of so auspicious an occasion to congratulate the Society upon having completed a first century of existence and usefulness, which it can do the more sympathetically, having itself already experienced the emotions coincident to a semi-centennial anniversary. The Society is to be congratulated, not merely upon being mature, but also upon being vigorous, and there is every reason to anticipate, from a useful past, a no less useful future.

In our modest effort to bring before the minds of our readers, to some extent, the social and professional conditions amid which the Society was born, it seemed eminently appropriate that the JOURNAL should group its material around the picturesque figure of the first president of the Society, Dr. Holyoke, whose own busy and prolonged career, marked as it was by a true temperance and prudent moderation, may not unfitly typify a destiny which it is to be hoped awaits through a longer cycle and in a larger sphere the body over which he first presided.

The JOURNAL takes this opportunity to thank the Essex Institute of Salem, and individual members of the Medical Society, for kind contributions to this anniversary number.

BIOGRAPHY OF DR. EDWARD AUGUSTUS HOLYOKE, FIRST PRESIDENT OF THE SOCIETY.¹

EDWARD AUGUSTUS HOLYOKE was the second of eight children of Edward and Margaret Holyoke, of Marblehead, County of Essex, Mass. His father was born in Boston, educated at Harvard College, where he was afterwards tutor, settled as pastor of the Second Congregational Society in Marblehead, April 25, 1716, installed President of Harvard College 1737, and died June, 1769, aged eighty. His paternal ancestor came from Tamworth, on the borders of Warwickshire, England, and was among the original grant-

ees of the town of Lynn, where he settled at Sagamore Hill, in 1638. President Holyoke was three times married; the first time to Elizabeth Brown, of Marblehead, the second to Margaret Appleton, daughter of Colonel John Appleton, of Ipswich, and the third time to the widow of Major Epes, of Ipswich Hamlet. The subject of this memoir was the offspring of the second marriage, and was born August 1, 1728, Old Style. In 1742 he entered the freshman class at Harvard University. He has preserved an account of his examination, and the sentence which was given him as a theme upon that occasion seems to have been the motto of his future life: *Labor improbus omnia vincit*. From this period to the end of his life he was characterized by constant diligence and assiduous attention to his duties. In 1746 he was graduated, and in the following year he spent six months at Roxbury in teaching a school.² In July, 1747, he commenced the study of medicine under the care of Colonel Berry, of Ipswich.³ This gentleman was the most distinguished practitioner of his neighborhood, although his being universally known by his military title does not speak highly for the estimation in which medical honors were then held. He finished his studies in April, 1749, and came to Salem in June of the same year. . . . For the remainder of his life he scarcely left the town, unless on business connected with his profession, and during his life he never wandered so far as fifty miles from the spot on which he was born. His longest journey was to Portsmouth, in 1749, at which time he was absent five days. In 1755 he was married to Judith Pickman, daughter of Colonel B. Pickman, of Salem. This lady died in her nineteenth year, in 1756, soon after the birth of a daughter, which did not long survive her. In 1759 he was again married, to Mary Viall, daughter of Nathaniel Viall, merchant, of Boston. Upon this latter occasion he was absent from Salem a week, which is believed to have been the longest visit he ever made from home, except in 1764, when he went to Boston to be inoculated for the small-pox. The length of this visit was occasioned by a custom which then prevailed for newly-married persons to devote a week to receiving the visits and congratulations of their friends, or, as the phrase was, "sitting up for company;" a ceremony which Dr. Holyoke declared to one of the committee was "very tedious and irksome." By his second wife he had twelve children, most of whom died in infancy. Two daughters only survive,—the widow of the late Mr. William Turner, of Boston, and the wife of Joshua Ward, Esq., of Salem. Dr. Holyoke was perhaps led to select this town as his place of residence in consequence of the death of Dr. Cabot, which occurred just at the time of his finishing his studies; but so little were his expectations of employment realized that after two years' trial he appears to have had serious intentions of abandoning the place in despair of success, and to

² For which he received eighty-four pounds old tenor, — \$38.50, — out of which he paid his board at sixty-seven cents per week.

³ "Thomas Berry, Esq., was born at Boston, the latter end of the seventeenth century, and was graduated at Harvard College, 1712. He received his medical education under Dr. Thomas Greaves, of Charlestown. He settled at Ipswich, Essex County, where he had a remarkable run of practice in his profession, and was considered the most eminent physician in that vicinity. But in the latter period of his life he was more attentive to politics than physic. He represented the town in the legislature, and afterwards was of the council several years, was judge of probate for the County of Essex, and justice of the court of Common Pleas, and colonel of the regiment. He died August 10, 1756, aged seventy-two." (From a memorandum of Dr. Holyoke's.)

¹ Taken from a memoir prepared by a committee of the Essex South District Medical Society, published 1829.

have remained here only through fear of distressing his father if he returned home.

No man probably ever entered upon the business of his profession with more settled resolution and perseverance than Dr. Holyoke. He had youth and health, a constitution of mind and body eminently calculated for endurance of labor and fatigue, was reputed a good scholar for his time; he read the Latin language with great fluency, and he subsequently attained a familiar acquaintance with the French; he had as many opportunities of learning his profession as were common at that time, and was respectably connected and advantageously known. But notwithstanding these advantages the medical profession abounded in discouragements which, to say the least, are greatly lessened in our day. The standard of medical education was totally unsettled. Every one who chose to prescribe for the sick was admitted to the rank of physician; the higher points of medical character and the value of medical studies were totally unappreciated by the bulk of the people, and the compensation for medical services was exceedingly small.¹ The periodical press did not then, as now, issue its regular current of observations and intelligence, and it was not till Dr. Holyoke reached the declining period of life that this species of medical literature had given that impulse to the profession which is so sensibly felt at the present day. It was rare, in the period of his meridian life, for any man to devote himself to medicine as a science, and pursue the profession without reference to other advantages than those which appertain to medical and scientific character. During almost the whole period of Dr. Holyoke's life the spirit of commercial adventure was the characteristic trait of almost all around him. There were many ways of rapidly attaining to wealth and distinction which looked more inviting than the one he had chosen; and it shows his steadiness of purpose, and his characteristic contempt for mere money, that during his whole life he never appears to have been enticed to engage in any of the enterprises which were undertaken by others in pursuit of wealth, or for a single day to have laid aside his character of a practitioner of the healing art. . . .

The characteristics of mind most essential to form the practical physician are a talent for observation, a readiness to take cognizance of the phenomena of nature, and curiosity to investigate the causes of these phenomena. These characteristics distinguished Dr. Holyoke from his outset in life. He had a good memory, and although his incessant calls prevented his devoting much time to writing, he seldom passed a day, for the first sixty years of his practice, without noting down some fact or observation calculated to augment his professional knowledge. His meteorological observations were recorded daily, almost without an interruption, for eighty years.

The study of the book of nature has been the occupation of the enlightened physician in all ages, and a more complete method of pursuing this study can hardly be imagined than that of Dr. Holyoke. If his attendance upon professional practice had ever allowed him to have fully completed this plan, and prepared the general results of all his observations for publication, he would have furnished a most valuable treasury of medical knowledge. He kept a memorandum upon

his table in which was minuted down the name of every disease the moment he returned from making his call, the more remarkable being the subject of further memoranda, as their interest required or his leisure allowed. At some stated periods, as at the end of the year, he made out a summary from these daily memoranda, in which he ascertained by computation the number of cases of every disease. He also was diligent in obtaining correct bills of mortality. He was thus enabled to inform himself most completely of the changes which take place in the frequency of occurrence and the fatality of diseases.

Although for reasons which have been mentioned he did not often appear before the public as an author, he was not indifferent to the cultivation of medical science among its professors. As soon as the Medical Society of this State was formed² he contributed his full share to their published transactions. He wrote the preface to the first volume, and the first paper of that volume is his interesting account of the state of the weather, diseases, operation of remedies, deaths, etc., in Salem for every month of the year 1786, and shows that he must have been in habits of close observation and of noting down the occurrences he met with in practice. Observations of the same kind were communicated for the years 1782, 1783, 1784, 1785, 1787, and 1788. Every physician engaged in full practice, as was Dr. Holyoke at this time, will admit this to have been no small labor.

By this method of increasing knowledge, and by more extensive reading than was common at that day, he was, in the early part of his career, in advance of most of his professional contemporaries. He acquired the authority of a master; and without being the leader of a sect his opinions were adopted, his prescriptions copied, and his practice imitated. His treatment of dysentery may be taken as a specimen of his early practice; a practice which he found successful, and which is still held in high repute by many practitioners of this neighborhood.

The terrible epidemic of sore throat of 1734-35, which almost totally destroyed the infant population of the north part of Essex County, was keenly remembered for many years afterward, and the attention of physicians was directed to the inflammatory affections of the throat and lungs, and the operation of remedies the most efficacious in these dreaded and dangerous attacks. Hence originated a more complete acquaintance with the mercurial practice than elsewhere obtained. . . .

Although, as has been observed, Dr. Holyoke was a cautious practitioner, he was not a timid one, and never neglected to make himself acquainted with the reputed powers of new articles which were from time to time introduced into the *materia medica*, and with the new modes of practice which were recommended by others. In the use of the digitalis, of the gum acaroides, of the muriate of barytes, and of many medicines of later date, he was one of the earliest and most careful experimenters. His use of acetate of lead in restraining hemorrhages, of the oxymuriate of mercury in the treatment of serofula and some forms of cutaneous disease, of small doses of calomel in the ulcerous oris of children, have led to the establishment of

¹ In 1780, when Dr. Holyoke was charged at five shillings a day, equal to about \$12.50, he received for his services only one shilling, equal to about \$2.50. He was at a time when the value of the dollar was about its present price, and other necessities were at a low rate.

² Dr. Holyoke was one of the founders of the Society, and was most punctual in his attendance at the stated meetings of the Society at large, as well as those of the District Society in which he was included. To this latter body he was a generous benefactor during his life, and bequeathed to their library some of his most valuable books.

modes of treatment attended with the highest degree of benefit. There are several medicines which owe their introduction into use entirely to him, and may, in fact, be said to have originated with him, as he was the first to settle their best mode of preparation and administration. The article so well known by the name of the "white balsam drops," or "fennel balsam," is a strong solution of subcarbonate of potass with the addition of a little of the essential oil of sweet fennel, and is a valuable diaphoretic and carminative, especially to children. This was a favorite medicine during his whole practice. He obtained his first knowledge of it from a Mr. Wigglesworth, of Malden. Of a cheap method of preparing the saleratus or supercarbonate of potass he wrote an account for the Massachusetts Medical Society. This article has in this neighborhood nearly superseded the common carbonate, both in medicinal and culinary preparations.

Dr. Holyoke's prescriptions were, for the most part, put up under his own inspection, either by himself or his pupils. This practice was nearly universal, even in large towns, till the commencement of the present century, and if there were obvious disadvantages in the necessity which called for so much of the valuable time of the physician there were undoubtedly some benefits derived from connecting practical pharmacy with his more dignified duties. . . .

Dr. Holyoke was intimately acquainted with the qualities and preparations of all the drugs he was in the habit of using, and was extremely neat and skillful in compounding them. Although, perhaps, he used a greater number of remedial agents than enter into the prescriptions of the present day, he was by no means infected with the polypharmacy which was the prevailing fault of the physicians of his time. The following anecdote, related by one of his pupils, exhibits the simplicity of his practice: "When I first went to live with him, in 1797, showing me his shop, he said, 'there seems to you to be a great variety of medicines here, and that it will take long to get acquainted with them, but most of them are unimportant. There are four which are equal to all the rest, namely, mercury, antimony, bark, and opium; of these there are many preparations, however. Of antimony I think I have used thirty.' These are his words substantially. He ought to have added cantharides, but he was thinking of internal remedies." The same person adds, "I can only say of his practice, the longer I have lived, I have thought better and better of it."

In 1777 Dr. Holyoke applied himself to the business of inoculating for small-pox. He had himself been inoculated in April, 1764, by Dr. N. Perkins at Boston, and his careful minutes of this occurrence¹ illustrate the customs and practice of that day. In March, 1777, he took charge of the hospital which had been erected a few years before for small-pox inoculation, and conducted through the disease three classes, amounting in all to about six hundred, with only two

¹ This business was in those days considered a very weighty affair. Dr. Holyoke first wrote to Dr. Perkins at Boston, where in consequence of the small-pox having been for some time spreading, the selectmen had given leave for a general inoculation, to engage his attendance and receive his directions for the proper preparation of the system. By Dr. Perkins's directions he took a pill at night of five or six grains of calomel with antimony, and lived low. After some days of this process he was reduced sufficiently to receive the disease in the most favorable manner, and accordingly, *having executed his will*, he went to Boston, April 6th, and first went abroad after the small-pox April 23d, having had the disease in the most favorable manner.

fatal cases occurring. But the loss of these two, less than the average number, one of which occurred in his first class of two hundred, affected his sensitive mind with so much anguish as almost to occasion self-reproach and a resolution to abandon the undertaking. During most of the period of his patients remaining in the hospital he passed his whole time with them, night and day, and many persons in Salem, who were at that time under his care for inoculation, testify to his assiduous and skillful attentions. . . .

Dr. Holyoke was an early vaccinator. He was in the common practice of it in the beginning of 1802, if not sooner.

As a surgical operator Dr. Holyoke had more than a mediocrity of talent and skill. He never appeared to have any extraordinary preference for this branch of his profession, but as a matter of necessity held himself qualified for all the usual demands for surgical treatment. In fact, the opportunities for a display of surgical address are much less frequent in the population with which Dr. Holyoke has resided than might be expected from its number.

As an obstetric practitioner he was greatly esteemed, and upon this branch of his business he seems to have bestowed extraordinary attention. On his first coming to Salem this department of the healing art was entirely in the hands of ignorant midwives, and the physician was only called in extraordinary cases, or to rectify some of the blunders of these practitioners. He has preserved an account of the first forty-five obstetric cases which occurred to him. The first one which he "was persuaded to engage in" occurred 1755, after he had been six years in practice, and it was not till four years afterwards that he makes the record of a case which was the first "common easy birth which ever came under his management."² . . .

He received pupils during nearly all the period of his active practice, and some of the most distinguished physicians of New England were educated under his care.³

² LIST OF BIRTHS. The following is a list of births, occurring in ten years of his practice, from 1790 to 1801, and is a memorandum of some interest to medical men:—

Years.	Boys.	Girls.	Total.
1791	35	49	84
1792	53	54	87
1793	52	33	90
1794	45	51	96
1795	59	48	107
1796	47	53	100
1797	54	43	97
1798	53	47	100
1799	48	54	102
1801	46	35	81
	494	452	946

³ LIST OF PUPILS:—

Isaac Atherton,	came 1762, remained 3 years.
Joseph Orne,	came 1795, remained 5 years.
David Jewett,	came 1766, remained 3 years.
William Paine,	came 1768, remained 4 years.
William Clarke,	came 1772, staid few months.
Edward R. Turner,	came 1772, remained 3 years.
William Goodhue,	came 1772, remained 3 years.
Nathaniel W. Appleton,	came 1774, remained 3 years.
Francis Borland,	came 1774, remained 1 year.
Edward Barnard,	came 1774, remained 3 years.
Daniel Kilham,	came 1778, remained 1 year.
B. Lynde Oliver,	came 1778, remained 3 years.
Isaac Osgood,	came 1777, remained 3 years.
Nathaniel Parker,	came 1779, remained 3 years.
Thomas Farley,	came 1782, remained 4 years.
Abiel Pearson,	came 1782, remained 3 years.
James Griffin,	came 1786, remained 2 years.
Ebenezer Learned,	came 1788, remained 3 years.
Nathan Read,	came 1787, remained 1 year.
William Harris,	came 1788, remained 1 year.
J. D. Treadwell,	came 1788, remained 3 years.

The period of the Revolution was a trying one to the subject of this memoir, and he never loved to dwell upon the recollection of it. His feelings in the spring and summer of 1775 were intensely painful. In referring to that period, he said to one of his family he thought he should have died with the sense of weight and oppression at his heart. He had sent his family to Nantucket, and the loneliness of his home increased the feeling of desolation. Most of his intimate friends and near connections favored the royal cause, and his own education had attached him to the established order of things, and his peaceful temper shrunk from the turmoil of a revolution. He thought this country destined to be independent, but believed the proper period had not arrived, and that weakness and dissension were likely to follow what he considered a premature disunion. But in after times, when referring to these opinions, he was wont, with his usual ingenuousness, to say that the event had proved he was wrong in his prediction. He imputed to the Revolution a change in the manners of the people which will not be reckoned among its good effects. He thought there was a falling off in domestic discipline, and a relaxation of wholesome subordination among children, since the freedom of the colonies.

During this trying period he kept steadily occupied in his benevolent duties, and such was his prudence, his inoffensive manners, and the universal respect for his virtues that he did not meet with so much trouble as might have been expected from the unpopularity of his opinions. Although most distinguished men who had adopted the royal cause found it expedient to leave the country, it does not appear that he was ever impeded in the prosecution of his business or studies for a single day. Once only he committed himself, by signing an address, in common with a number of the most distinguished citizens of the town, complimentary to Governor Hutchinson, who was about leaving the country. He afterwards felt himself obliged, as well as most of his associates, to publish a sort of apology for this act, which recantation, as it was called, contained nothing that was servile or disgraceful.¹ It does not appear that his practice was ever injured by the part he took in politics. He held a commission as a magistrate both before and after the Revolution. . . .

Edward Wigglesworth,	came 1790, remained 1 year.
Nathaniel Lee,	came 1791, remained 2 years.
Thomas Peckman,	came 1791, remained 3 years.
John Preston,	came 1791, remained 3 years.
James Cook,	came 1795, remained 3 years.
John Jackson,	came 1797, remained 2 years.
Nathan Badstreet,	came 1798.
Samuel Gorsh,	came 1799.
Melchor Spalding,	came 1800.
Samuel Hildway,	came 1801.
Samuel Frost,	came 1804, remained 2 years.
— F. A. G.,	came 1804.
John B. Brock,	came 1808, remained 1 year.
Edward A. Hildway,	came 1817, remained 1 year.

Enclosed, &c.

RECANTATION OF FORBISM, SALEM, MARCH 30, 1775. When as we, the undersigned, had on the 20th inst. signed an address to Governor Hutchinson, who, though prompted to by the best intentions, has nevertheless, in our opinion, committed an offence to our country. We do now declare, that we were so far from desiring by that action to show our approval of the acts of parliament, so universally and justly reprobated by America, that on the contrary we hoped we might in that way contribute to their repeal; though, in view to our sorrow we have been disappointed. And we now further declare that we never intended to show such a tribute to his excellency, and that if we had been apprized of the nature of the address, we should never have signed it; as we were well aware, that we contributed thereby to the injury of our country. We now, therefore, withdraw our names from the address, and in the fullest manner disavow it, and we are, as we have said, rejoiced with the revocation of it.

Signed by twelve persons.

The circumstance of his arriving to be an hundred years old,—an occurrence so unusual to happen to any man,—and of which it does not come within the knowledge of the committee that there are many authentic accounts of its having happened before to eminent physicians, was looked upon by the doctor and his friends as an era of very great interest. Upon this occasion his medical friends of Salem and Boston united to pay their respect to him by inviting him to a public dinner. At this period he appeared in perfect health, and his firm and elastic step, his cheerful and benevolent looks, his easy and graceful manners, the model of the old school of gentlemen, his nicely-powdered wig, his dress arranged with studied neatness, and just enough of antiquated fashion to remind one that he belonged to the generation gone by, but not outraging the proprieties of the present mode, his accustomed nosegay slipped through his button-hole, and his affectionate and grateful greeting of those who had assembled to do him honor, will never be forgotten, or remembered without delight, by those who witnessed them. He partook of the hilarity of the occasion with an evident zest, and when called upon for a toast, offered in his own hand-writing a sentiment perfectly appropriate and professional, accompanied with a paternal and touching benediction upon the medical brethren who were present. At the same time the District Medical Society testified their respect for him by requesting him to sit for his portrait, to be placed in their library. . . . The anniversary of his birthday was on the 13th of August, and on the 18th of September, the centennial anniversary of the settlement of the town, he was again induced to take part in the public celebration. . . . The excitement of these occasions appeared rather to invigorate him than otherwise, and he afterwards visited Boston and Cambridge, and the place of his birth; upon all which occasions he enjoyed much gratification. This was, however, the last lighting up of the spark of life, and in about a month he began to feel the approach of that disease which terminated his life. . . .

In seeking for the causes of his length of life and enjoyment of health, it seems obvious that he owed these to a rare combination of natural advantages with the habits of life best calculated to preserve these advantages. He was a happy example of a sound mind associated with a sound body, neither of which was matured or maintained at the expense of the other. . . .

He required and sought but little relaxation from professional occupations, and these of the simplest kind. Occasional short visits to the neighboring towns where his connections resided, a weekly evening conversation club,² and the culture of his garden were his principal resources for amusement. As an indoor recreation he was fond of the sober game of chess, which was the only game of skill he was accustomed to play at. He now and then indulged in a party upon the water in summer, and for many years of the early part of his life, in his favorite exercise of

² Dr. Holyoke took great pleasure in the meetings of his Monday night club. Their object was improvement in philosophy and literature by reading and conversation. Some of the most amiable and distinguished individuals who ever belonged to this town were associated in it. Their meetings were interrupted by the breaking out of the revolution, and commenced again in 1779. During the period of their suspension, or at least a part of it, so strong were the Doctor's attachments to the memory of his friends that he was accustomed to devote the usual evening of their meeting every

skating upon the ice in winter, in which exercise he was well skilled. He sometimes, too, upon festive occasions, till he thought his age rendered it unbecoming, mixed in the sprightly dance, of which he was said to be fond. . . .

Of his temperance there is one remark which we think it of consequence to make, since it shows the error of those who think that temperance consists in relinquishing some articles of food or drink, while they indulge to an injurious excess in others. His was a temperance of *moderate desires*, that never led him to err in *quantity*, and thereby rendered him less solicitous about the *quality* of his food. The following letter, written last autumn, in answer to one he received from a gentleman, who had addressed to him some inquiries concerning his habits and mode of life, gives a satisfactory and interesting account of these matters. . . .

SALEM, Oct'r — 1828.

To — — —, Williamsville, Person County,
North Carolina.

SIR,—I received yours of the 20th ult. on ye 30th, wherein you wish me to give you some Account of my Mode of Life, &c. — In answer to which I would first mention that I was providentially blessed with an excellent Constitution — that I never injured this constitution by Intemperance of any kind — but invigorated it by constant Exercise, having from my 30th to my 80th Year walked on foot (in the Practice of my Profession) — probably as many as 5 or 6 miles every day, amounting to more than a *million*¹ of miles, and tho' sometimes much fatigued, the next Night's refreshing Sleep, always completely restored me. In early life, between 20 and 30, I used to ride on Horse back, but being often pestered by my Horses slipping their Bridles I found it more convenient to walk.

As to my Diet, having been taught to eat of any thing that was provided for me, and having always a good Appetite, I am never anxious about my food, and I do not recollect any thing, that is commonly eaten, that does not agree with my Stomach, except fresh roasted Pork, which tho' very agreeable to my Palate, almost always disagrees with me; for which however I have a remedy in the Spirit of Sal Ammoniac. Eight or Ten drops of Aqua Ammonia pura in a wine glass of Water, gives me relief after Pork, and indeed after any thing else which offends my stomach. As to the Quantity, I am no great Eater, and I find my appetite sooner satisfied now than formerly; — there is one peculiarity in my Diet which as it may perhaps have contributed to Health I would mention; I am fond of Fruit, and have this 30 or more years daily indulged in eating freely of those of the Season, as Strawberries, Currants, Peaches, Plums, Apples, &c. which in summer and winter I eat just before Dinner, and seldom at any other time, and indeed very seldom eat any thing whatever between meals. — My Breakfast I vary continually.

week to conversing about them with his family, who were assembled for the purpose. . . .

Among the names of the persons who constituted Dr. Holyoke's club and his intimate acquaintance, in those days, were those of Andrew Oliver, Judge of the County Court, Nath. Ropes and Benj. Lynde, Judges of the Superior Court, Rev. Wm. McGilchrist, of the Episcopal Church, who was educated at Oxford and distinguished as a mathematician, Rev. Thomas Barnard of the First Church, Rev. Dr. Barnard of the North Church, Dr. Ernestus Plummer, Dr. Putnam, who was cotemporary with Dr. Holyoke, Mr. Wm. Pyncheon, an eminent lawyer, Col. Pickman, Col. Frye, Col. Browne, afterwards Governor of Bermuda, Col. Eppes Sargent, Col. Ichabod Plaisted, Mr. Stephen Higginson, Mr. Thomas Robie, and Mr. Samuel Curwen. More than half a century ago an eminent Boston divine used to say there was no pulpit in which he should not choose to preach an ordinary sermon sooner than that of Mr. Thomas Barnard of the First Church in Salem, to whose parish most of these men belonged. Many of them were men of accurate literary attainments, great critical acumen, and of considerable research in theology.

¹ This seems to have been a slip of the pen; the following is his own calculation, made in 1823, and which from his great dread of exaggeration falls short of half the actual amount. "If from my age of 20 to 80 years I have walked 5 miles a day, which is a moderate calculation, I must have gone in that 60 years

	109,500 miles.
And in the first 20 and last 15 years . . .	38,325
In 95 years probably, total . . .	147,825"

Coffee, Tea, Chocolate, with toasted bread and butter, Milk with Bread toasted in hot weather, but never any meat in my Life — seldom the same breakfast more than 2 or 3 days running. Bread of Flour makes a large portion of my Food, perhaps near 1-2. After Dinner I most commonly drink one glass of Wine — plain boiled rice I am fond of — it makes nearly 1-2 of my Dinner perhaps as often as every other Day — I rarely eat Pickles or any high seasoned Food — Vegetable food of one kind or other makes commonly 2-3 or 3-4 of my nourishment — the condiments I use are chiefly Mustard, Horse radish and Onions. As to Drinks, I seldom take any but at meal times and with my Pipe — in younger Life my most common draft was Cider, seldom Wine, seldom or never Beer or Ale or distilled Spirits — But for the last 40 or 50 years, my most usual drink has been a Mixture, a little singular indeed, but as for me it is still palatable and agreeable, I still prefer it — The Mixture is this, viz. Good West India Rum 2 Spoonfuls, Good Cider whether new or old 3 Spoonfuls, of Water 9 or 10 Spoonfuls — of this Mixture (which I suppose to be about the strength of common Cider) I drink about 1-2 a Pint with my Dinner and about the same Quantity with my Pipe after Dinner and my Pipe in the Evening, never exceeding a Pint the whole Day; and I desire nothing else except one glass of Wine immediately after Dinner the whole day. I generally take one Pipe after Dinner and another in the Evening, and hold a small piece of pigtail Tobacco in my mouth from Breakfast till near Dinner, and again in the Afternoon till tea: this has been my practice for 80 years — I use no Snuff — I drink tea about sunset and eat with it a small slice of Bread toasted with Butter — never eat any thing more till Breakfast.

I have not often had any complaint from indigestion, but when I have, abstinence from Breakfast or Dinner, or both, has usually removed it; indeed I have several times thrown off serious Complaints by Abstinence. — As to Clothing, it is what my Friends call thin; I never wear Flannel next my Skin tho' often advised to it, and am less liable to take cold, as it is called, than most people — a good warm double breasted Waist-Coat and a Cloth coat answers me for winter, and as the season grows warmer I gradually conform my Covering to it. — As to the Passions, Sir, I need not tell you that when indulged, they injure the Health; that a calm, quiet self possession, and a moderation in our Expectations and Pursuits, contribute much to our Health, as well as our happiness, and that Anxiety is injurious to both.

I had a good Set of Teeth but they failed me gradually, without Pain, so that by 80 I lost them all.

Thus, Sir, you have, blundering and imperfect as it is, an answer to your Requests, with my best wishes that it may be of any service to the Purpose for which it was made — But must rely upon it that Nothing I have written be made public in my Name. Wishing you long Life and many happy Days,

I am yours, &c.

E. A. H.

P. S. I forgot to speak of my repose. When I began the practice of Physick, I was so often call'd up soon after retiring to Rest, that I found it most convenient to sit to a late Hour, and thus acquired a Habit of sitting up late, which necessarily occasioned my lying in bed to a late Hour in the Morning — till 7 o'elk in Summer and 8 in Winter. My Business was fatiguing and called for ample repose, and I have always taken care to have a full proportion of Sleep, which I suppose has contributed to my longevity.

In summing up the character of our venerable friend, it is not too much too much to say, he was a perfect model of the general practitioner of medicine. His manners were equally removed from servility and arrogance. Free from dogmatism, and trusting to the mild dignity of his manners to enforce his precepts, nothing excited his displeasure more than the swaggering, *Radcliffe* style assumed by some men to impose an idea of their consequence upon the vulgar, who are sometimes prone to believe that excessive rudeness is a mark of genius, and that consummate insolence is, not unfrequently, coupled with consummate skill. These people he used to term "medical bucks."

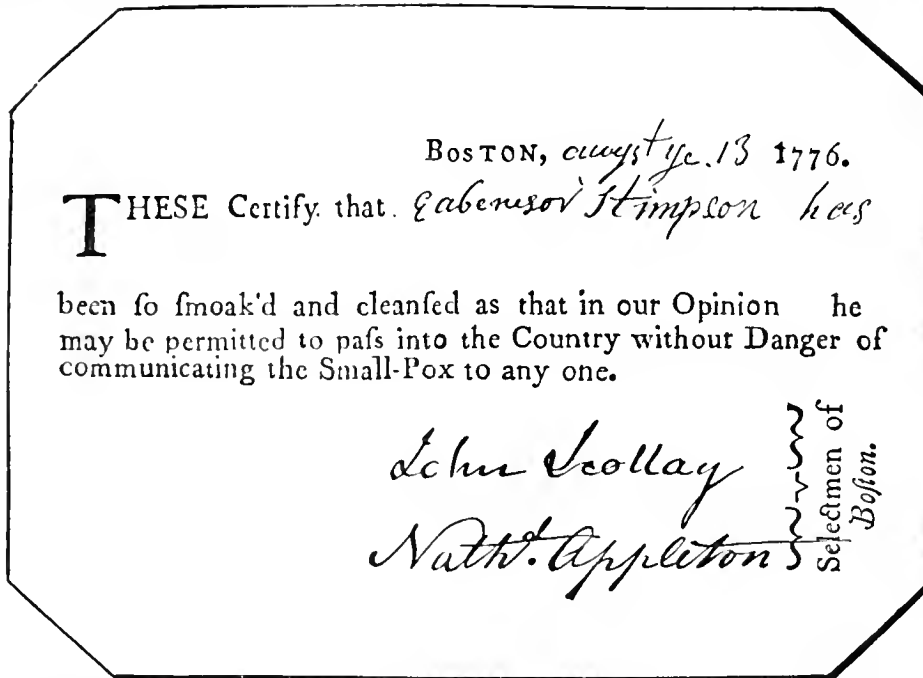

His regard for truth was scrupulous and sincere, and this was obvious in his reasoning upon facts, for he was never known to form a deduction which required the sacrifice or modification of an important fact in the premises; but he rather suffered his judg-

ment to remain suspended, and waited for a farther insight into the operations of nature. From the same cause, a letter of recommendation or introduction coming from him, even in behalf of the most valued of his friends, was sure to contain not one word more than came within the scope of the author's personal knowledge and observation.

His generosity and the moderate competence with which he contented himself prove this. Still more peculiar was the perfect simplicity and singleness of heart which marked his moral conduct. There was no effort, he acted right because he felt right, and every one could see that the kindness of his manner was a sincere expression of the kindness of his heart. It was the perfect confidence which every one had in the habitual rectitude and purity of his intentions that induced persons of all ages and of all classes to look upon him as a sympathizing friend to whom they might safely intrust their most important interests.

His sickness and expected death were the most common topics of inquiry with the citizens of Salem for some days previous to his decease; and when this event took place, it was announced by the tolling of all the church bells of the town, a mark of respect never known to have been shown to any others than the late Presidents of the United States. All classes of persons thronged to his funeral to pay their tribute of respect to his memory, and the eulogy pronounced over his remains by his pastor and intimate friend, the Rev. Mr. Brazer, was a chastened effort of genuine and touching eloquence, and a delineation of his moral and religious character, which was recognized as faithful and just by the crowded assembly before whom it was pronounced. . . .

The accompanying fac-simile of a certificate of fumigation serves to show that our ancestors took such precautions as the knowledge of the time allowed them.

As a fitting accompaniment to the certificate of fumigation we are enabled to publish a letter addressed to Dr. Parker, a practitioner of Virginia, transmitting vaccine virus. The letter is interesting as containing in few words directions which are just as applicable to-day as at the time they were written, and as illustrating the efforts of President Jefferson to favor vaccination.¹

LETTER FROM MR. J. W. EPPES (SON-IN-LAW OF THOMAS JEFFERSON) TO DR. PARKER OF VIRGINIA

J. W. Eppes with his best wishes forwards to Doct^r Parker a phial of Genuine Cow pox matter.

It has been taken from subjects inoculated from matter forwarded by Doctor Waterhouse of Boston to the President. It has been fairly tried by Waterhouse who has inoculated several hundred with the small pox matter after their having gone thro' the cow pox,

¹ The letter is furnished for publication by Dr. Parker of Plymouth.

without the small pox infection taking in a single instance.

One peculiarity attends the disease. The virus must be taken from the pustule for inoculation while quite clear and transparent. If taken after complete puffs is formed it gives a bad fore without communicating the disease. The 7th or 8th day is as late as the matter can be taken for inoculation with safety.

Accept for your health the best wishes of a friend.

Endorsed on back. *J. W. Eppes*, Son-in law to Thos. Jefferson, M. C. & was chairman of the committee of ways & means in Congress.

Endorsed in another corner. Cow Pock.

From the Independent Chronicle and the Universal Advertiser, Jan. 1781.

A young Woman with a good Breast of Milk would take a Child to suckle.

Inquire of the Printer.

PORTION OF THE DIARY OF MR. PYNCHON OF SALEM, COVERING THE PERIOD OF HIS STAY IN BOSTON FOR THE PURPOSE OF INNOCULATION.¹

[Day 1.] July 15, 1776. The weather fair and fine. Went to Winesmet from Salem with son John driven by Billy — Arrived at Boston in good season — We were inoculated at Dr Loyds house at ten o'clock in ye even'g — he gave me six powders to be mixed wth Moll^a & taken one each night & morn'g — three for John for Monday Wednesday & Friday nights.

[Tuesday, 2.] July 16th. Johns powder operated o(nce) — mine 3 times — very moderately — went to see Mr. Vassals fine garden also Mr Lowells — eat our fill of fine fruit A. M. — visited ye Salem patients in K & Q Streets & find yt they take powders but once in 2 days yt I am fav^d as to medicine but expect to pay for it in pocks — dined at our lodgings.

[Wednesday, 3.] July 17th. (Dr.) Putnam took ye bandage &c off my arm this morn'g — was satisfied yt ye incision &c. were effectual — went to Dr. Loyd & he was of ye same mind. Visited our friends, patients &c in K Street & Q street — also Dr Pemberton & Dr. Mather — dined at M^r Thos. Ruffels with Dr Putnam Mr. Sparhawk & Mr. Coleman —

P. M. eat fruit at Mr. Sheriff Greenleaves fine Garden — I mean S. Greenleafes esq^r — wrote to M^{rs} Pyn. by Cap^t Peale for some currants &c. Dr. Putnam & bro Sargent at my lodgings ye eveng — drank Tea at Dr Putnam's.

[Thursday, 4.] July 18th. Took a glass of fenna this (morn'g) instead of ye powder — ye . . . having had no effect since last Monday P. M. — John took half a glass of it also — & within 2 hours each of us took another glass of it also — wrote to M^{rs} Pyn — by M^r Johnston & by M^r Sparhawk for Currant Syrup instead of ye fruit — our Physick affects both this morn'g — met Dr Goodhue riding out — he is break'g out & is relieved by it — his symptoms have been very high these 3 days — yt appeared ye 9th day from ye inoculatⁿ.

At noon the Congress Declaration of ye Independence of the Colonies on G. Brit. was read in ye Balcony of T^o house — A Regim^t under arms & artillery C^o in King street & ye Guns at the sea batteries were fired — 3 Cheers given Bells ringing &c. &c. afternoon ye Kings arms were taken down & broken to pieces in K street & carried off by ye people.

[—.] July 18th. ano. glass of fenna. Dr Loyd came to see me — ordered me to continue taking ye powders of fenna. John to go on with ye fenna but to omit ye powders till Sat'y night.

In ye eveng recd letter from Mrs. P. & a box of Jellies &c per Mr. Knox.

Fryday 5. [July 19.] Took another glass of fenna. . . .

John took one also — it being . . . was affected with yesterdays Physick. At 12: took a powder.

Mr. Hunt's at Tea — Met Mr. Otis & was introduced by him to Mrs. Otis in ye street he left us telling her that I was once a handsome fellow.

On Saty. eve at Dr. Loyds I met Mrs. Otis & she urged me to come and see him.

[July 20.] We took each of us a glass of fenna before breakt — at 11 I took a powder wrote to Mrs. Pyn. by Mr Sanders.

A. M. Was at Mr Bromfields and at Mr — in Q. street, also at Mr. Sparhawks.

P. M. We went over to Bunker hill, met Mr Barrett & wife at ye ferry w^o had been at my lodgings to see me & was going to Salem on Monday. On our return from C-town found yt Dr Loyd had been to see us in ye even'g I went to advise with him as to medicine for to night & to morrow but c^d not see him.

At 10 Jno. took his powder & I, a glass of fenna Billy this afternoon brot us some curr^t fyrrup & currants & a p^r shoes for Jn^o & returned — My medicine operated once & Johns to day.

[July 21.] John complains of swelling (of) his arm & in his gums & — Toothach each of us took a glass of fenna at 9 at 1 Dr. Loyd called & left 6 more powders for me & some salts for John — the powders to be taken even'g & morn^g as before — ye salts at twice 2 an oz. at a time.

P. M. A Transport of — tons laden with Beef Butter & — from Ireland was convoyed into Nantasket by a fisherman, on discover^s ye imposition w^d have gone off but was prevented by ye Fort at 1st on her comg to ye wharfe Guns were fired & three cheers were given.

[Monday, 8.] July 22^d. Wr. fair. [It i]s a very hot day — The militia being mustered for procuring — men this Town's proportion for Canada & N. York drew us all into ye Common & ye great heat brot on John's symptoms to wit headach & fever, took away his appetite — the dose of salts wth he took in ye morn'g soon fet him a vomiting then took a glass of fenna & was affected but once by any of his med^{co} dozed all ye rest of ye day — at Night took a small dose of nitre dissolved in water — went to bed havg but one dish of Tea & a little p^{ce} of cake since breakfast My med. affected me but once to day it being a glass of fenna & a powder in morn'g & eveng — was at M^r Brimmer's, P. M. — Jno. was very feverish & restless at Night.

Jno. was shiverg & somew^t cold, A. M.

[Tuesday, 9th.] July 23. W^r cloudy & cool.

Each took his glass of fenna. I took my powder as usual — twice — attended ye court of inquisition. Johns fever very high all night — vomited in ye even'g.

July 24th. headach & loss of appetite early yet assisted & gave directⁿ to Mr Elliots Comand^{rs} of y^e Privateers — walkd only to y^e ferry this morn — both languid & weak — effects of medicine 4 times — drank to day only 2 dishes of Tea & about 4 spoonfulls of milk porridge being sick at ye Stomach — puked once.

John continues to breakfast — Mrs Pyncheon came with Billy & brot some fruit.

[Thursday, 11.] July 25th. W^r warm — sicknefs & headach contin[ues] Jno. is easier yⁿ yesterday & continues to break out — eat to day about a gill of milk & water & a little p. of milk biscket — ye like at night headach & pains in my Limbs abates in ye cool of ye Even^g & I rested well — Dr. Loyd had his Trial this afternoon before ye Court of Inquisition — began to shave myself in ye morn^g but being obliged to desist thro' weakn^s & faintnefs was shaved by Barber P. M. —

¹ A portion of this diary was written in cipher, which has been translated for this number of the JOURNAL by the kind permission of the owner, Dr. F. E. Oliver, of Boston.

Miss Sargent Lowell W. F. & Lad^s & Dr Elliot & Neighb^r Giles & Misses Orricks made us visits.

[Friday, 12.] July 26th. headach & pain in my bones return without any appetite — eat only some broth at noon a dish of tea & one of coffee P. M. sleep well.

[Saturday, 13.] July 27th. W^r moderate.

Symptoms continue [—eat some milk & water with Jonee cake for breakfast on searh Dr Loyd finds some pustules in my neck & on ye shoulders — Dr Loyd much affected wth ye illn^s of his children hav^g. ye throat diltemper — hear from Salem yt Derbys prize was retaken near Newbery barr.

feet in warm water this eve'g.

[Sunday, 14.] July 28th. W^r Fair. — early — symptoms continue — rose & walked about ye house till sunrise — then walked to Charlestown ferry eat some whitpot for breakfast also a cup of coffee & cake Dr P. says my fever is much abated more pustules come out had a stool at noon M^r W & Caty came to see us.

broth for dinner — Jno. eat in additⁿ to his broth a little Lamb & cucumbers notwithstanding my object. had 2 more stools — moderate. in ye morn^g Mr. Lowell brot me some gooseberr^s & cherries.

feet set in warm water.

[Monday, 15.] July 29th. Waked & rose at 3. head[ache] walked to Ch-ferry — 1½ dish of coffee for breakf^t Pudding for dinner — Jno fever increaseth & his pustules very fore — Dr Loyd here — Mr Wetmore & lady set out for Salem abt. 9 o'clock just before ye shower Johnny's fever & fores increaseth Dr Loyd & Dr. Putnam came in ye even^g & proposed med to open his bowels & he had a costive stool in ye N^t.

drank 1 dish of Tea — this & fruit was all yt I eat after Dinner.

[Tuesday, 16.] July 30th. W^r fr. pain in my head not entirely gone — for breakfast 1 dish of coffee 2 dishes of milk & water with milk biscuit & a bun Jno took electuary — Dr Loyds trial finished — his condemnation

I eat for dinner pudding & some butt^d peas M^r Sargent went with me to see Judge W. Cushing whose pork was about turn^g —

I slept ill this night by reason of gt costiveness and this I am now satisfied to have been owing to a large quantity of Genison pairs which I eat some days past wth I find by experience to be very binding, tho ye Drs. seem doubtful of it.

[Wednesday, 17.] July 31st. Had a stool early — rose with my headache as usual. Billy came from Salem — brot some fruit & dined with us.

Dr. Loyd here to see us.

[Thursday, 18.] Aug. 1st. fast day — W^r fr. & warm — rose with headach — had 2 plentiful stools — Dr. Loyd came & allow^d of eatg meat oylers & mol^d. P. M. — went with Dr. Putnam to hear Dr. Elliot — coddled apples & milk sup^r

Thun^rered & rained in ye night

Aug. 2d. go to bed but cant sleep rise agn. & walk ye room some hours — took elect^y. twice to day.

[Saturday, 20.] Aug. 3d. W^r fr. rise with ye headach — had 1 stool early — took elect^y twice — ch^d for breakf^t. walked up to K Street Mr Low^e & N^t. by way of Dr Putnam were ask^d to Dr Loyds this afternoon but were not well en^o to wait on him — letters from Caty at Salem Took elec

tuary at going to bed — supped on Coddled apples & milk

[Sunday, 21.] August 4th. W^r fr. & fine. slept well last N^t my usual headache — for breakfast. rode in Dr Pemberton's chaise to ye fortification & back wth son Jno. w^{ch} almost cured my headach — took electuary this morn^g dined on w. berry pudding Butter sauce, stringed beans & peas & roast pigⁿ & eat heartily without inconvenience & drank a Baker of wine & water

Tea at home M^{rs} Pyn. & Jno. at Miss Gunther Dr. Loring & ye Miss Hunts spend ye eveng with us — Took elect^y. at even^g. Suppr. W. & milk.

[Monday, 22.] August 5th. [Rose] at 6 — almost free of headach — cho. for breakf^t at 8 went over ye neck with Mr Coborns horse & chaise — a glass of fenna before breakf^t Mutton Squash & Turnips for Dinner wth a little slip at Landlady desire & it did no harm — Tea at D^r Loyds where were D^r Pemberton &

Chocolate for Supper — took electuary — first — N. Ropes came with chaise for D^r Putnam & Eben.

[Tuesday, 23.] August 6th. rose without headach to Ch-ferry with Dr Putnam Took a glass of Senna. Choc for breakf^t. rec^d a present of fermons from D^r Pemberton — at eleven took electuary Billy & Sally came & dined wth us at two tarried ye night.

[24.] August 7th. chocolate for breakfast — Billy & Sally tarried at breakfast & Dinn^r & they with John set out for Salem after dinner with S. Cabot & Deb. Higginson abt 4 o'clock from W^t. P. M. Electuary I was at Dr Clarkes P M & eat fruit in his Garden.

[Friday, 25.] August 9th. W^r cloudy — rose at 7. being first well washed all over in Rum & Water — put on clean Linen & Clothes — Mr Wetmore dined here.

August 10th. I rose at 1-2 after 8 o'clock too late to breakfast at M^r Elliots w^o invited Mr W. & myself we all dined at Mrs Chadwells & about 2 set out for ye ferry. Mr. W. & Mrs Pyn. for Charlestown myself & Billy for Winn^d. & we all met at Newhalls & baited & reached Salem abt 7 o'clock

Fryday, Aug. 23d. after — several poultices the scabbs — difficulty was pulled — arm & was buried —

From the Chronicle and Advertiser.

The Boston Medical Society having taken into consideration the general wish of the inhabitants that an annual settlement of their accounts might establish a custom in this Town. — Resolved, that the following Vote be published viz.

That every Member of the Boston Medical Society shall exhibit his accounts for settlement annually.

Per Order

THOMAS KAST Sec^y, Jan. 8, 1784.

Last Wednesday Se'nnight departed this Life Mrs. Hannah Davis, the amiable Consort of the Honorable Caleb Davis, Esq: of this town — Her Remains were Entomb'd on Friday Evening being followed to the silent Mansion by a numerous and mournful Procession of Relatives and Friends, whose unaffected Sighs and Tears feelingly Evinc'd that she died greatly lamented.

Nov. 7, 1782.

MEDICAL SOCIETIES: THEIR ORGANIZATION AND THE NATURE OF THEIR WORK.¹

BY J. COLLINS WARREN, M. D.

"THIS may be considered the birthday of medical honors in America," wrote the provost of the University of Pennsylvania, in recording the first medical commencement held in its college hall on June 21, 1768, and the occasion did mark the beginning of a new era for medicine.² Two years before a State medical society had been formed in New Jersey,³ but with this and one or two trivial exceptions, no attempt had been made to organize or instruct medical men on this side of the Atlantic. Previous to this period, those who desired a medical diploma were obliged to seek it in the mother country; but out of the three thousand physicians then in practice, it has been estimated that not over four hundred had received the degree of M. D. from a medical college.⁴ Many of the practitioners of medicine were also clergymen, taking charge of the bodies as well as the souls of their patients.⁵

But the incubation period of two centuries was nearly over, and the work of organization and teaching had already begun. All classes in society were beginning to feel the quickening influence of the infant republic, which was soon to be added to the family of nations. In New England we were less fortunate than elsewhere; the means of obtaining a knowledge of medicine were more limited and deficient than in the middle and southern provinces;⁶ but with the Revolutionary War came a demand for medical services, out of all proportion to that which had previously existed, while the establishment of military hospitals afforded an opportunity to study disease. As the tide of battle swept towards the South, and the period of war was drawing to a close, the new order of things began to shape itself in this part of the country. The military combinations, which finally culminated in the surrender of Cornwallis, were already in course of development, and the final scenes of the military drama were rapidly following each other, when medical science in this State first crystallized into definite form.⁷

The Massachusetts Medical Society was organized by the better educated portion of the physicians of the State, for the purpose of establishing a standard of

education⁸ in the midst of the then existing chaos. No system of medical education had previously been observed in the State, and no means whatever existed of ascertaining the qualifications of candidates for the profession. A young man might pursue his studies in such a manner and for such a length of time as he saw fit, and then enter upon practice without examination or license of any kind. It necessarily followed, from such a state of things, that a considerable number came into the profession who were altogether unqualified for its high responsibilities. Every new practitioner was an object of suspicion. The original plan contemplated the organization of an examining body, to determine the skill in their profession, and the fitness to practice it, of all candidates who should offer themselves for examination. It was intended that the successful candidates should receive the "approbation of the society," in letters testimonial of such examination. The members of this body, consisting originally of but thirty-one, and limited to seventy,⁹ were termed Fellows, whereas those who passed successfully its examinations did not become, as now, members, but were simply licentiates, or men announced by the society as fit to practice medicine. An election into this body was made honorary, and only conferred upon those who had arrived at some distinction in the profession. Some of the Fellows were distinguished members of other professions. It was formed somewhat after the model of the English educational bodies of that day, such as the Royal College of Physicians.¹⁰ This arrangement did not prove popular; there was an unwillingness, on the part of those already in practice, to submit to the examination of the society or to acknowledge the supremacy thereof, without enjoying professional equality with the Fellows. Such distinctions not being "in accordance with the spirit of the institutions" of the young republic. Accordingly, in 1803, the number of professional men in the State having greatly increased, a radical change was made in the constitution of the society, an extensive correspondence having been instituted among its members in order to devise the best means of increasing its usefulness.¹¹ The plan was to embody the whole of the regular profession in the State, and, by means of the authority derived from the legislature, to regulate the requirements of a medical education, so as to elevate the general character of the whole profession. For this purpose the limit of numbers was taken off, and every physician after three years of practice was entitled to enrollment as a member.

In the acts authorizing this important change we find the first public mention of the Councilors, although they constituted the working body of the society from its beginning.¹² To them, at all events, were intrusted many functions previously performed by the Fellows. It was evidently intended by those who wrought this change that the governing body, although all members

⁸ "That a just discrimination should be made between such as are duly educated and properly qualified for the duties of their profession and those who may ignorantly and wickedly administer medicine." (Act of incorporation 1781) (in italics in the original).

⁹ Acts of 1781, section 6.

¹⁰ Founded by Linacres, who died 1520. "That illiterate and ignorant medicasters might no longer be allowed to practice the art of healing." College of Surgeons incorporated March 12, 1800. The Royal Society was founded in 1645. An attempt was made about the year 1812 to incorporate a college of physicians in Boston, but, being vehemently opposed, both by the society and the medical school, it did not succeed.

⁷ "These societies were the principal agents in fixing the standard of medical education, and although, after the establishment of medical schools, the diploma of one in good repute was accepted in lieu of an examination, this was by courtesy rather than by law, and made it necessary that the standard of the schools should be at least equal to that prescribed by the societies." A Century of American Medicine. By John S. Billings, M. D. American Journal of the Medical Sciences, vol. lxxii. The American Academy of Arts and Sciences was established the year previous.

were now equal, should maintain that parental attitude towards the members throughout the State which the Fellows previously held towards their licentiates. They were chosen at the annual meeting, and exercised a general supervision over the affairs of the society. The election of all officers was in their hands, and it was left to their discretion to establish subordinate associations in such districts of the commonwealth as they might think expedient, or to subdivide or alter any them whenever the public good might seem to require it, and it was expressly provided in this early act that "the members of such subordinate societies be holden to report to the Councilors of the general society all such cases as may be selected for their importance and utility," showing the purpose for which these societies were to be formed, and the correlative duties which thus devolved upon them. The business of determining the qualifications of any individual who might apply for membership was delegated to a board of Censors, but the Councilors were permitted to elect those in practice at the time of the act and for some time after, and also honorary members.

The Censors consisted at first of a single board of five members.¹ We find them mentioned in the list of officers under the original plan of organization. As new district societies were formed additional boards of Censors were appointed.² In early time the Censors had great responsibilities forced upon them, for in 1817-18 general laws were passed by the State compelling the society to examine candidates for a license to practice, and depriving all who were not graduates of a school or licentiates of the society from legal privileges in collecting fees. In 1831 the clause requiring a successful candidate to practice three years before becoming a member was rescinded,³ and in this year, also, the Legislature compelled the society to accept the graduates of Harvard as members, but subsequently, in the acts of 1836 and 1859, it was provided that the society should not be allowed to discriminate in favor of any institution, and that all applicants should be treated alike.⁴ In the mean time, however, the State largely relinquished direct control over the practice of medicine, and as in the other professions gradually left it to take care of itself; since then the society has exerted its power for good in this direction solely through its influence upon public opinion and in maintaining a high standard.

The district societies owe their existence to the parent society. Their status was defined in 1803, as already indicated in speaking of the powers of the Councilors.⁵ "Before 1850 there were district societies only here and there in the State established at irregular intervals. In 1850 the Councilors divided the whole State into districts, in each of which they established a society. An addition to the charter of that year gave to the dis-

trict societies the privilege of choosing Councilors and Censors."⁶ This reorganization, as it were, of the districts was preceded in 1831, and again in 1848, by considerable discussion as to the relations of the districts to the parent society. One of the more active and powerful and at the same time one of the most distant subdivisions of the society was in Berkshire. It was apparently felt by certain members of this district that heavy burdens were imposed upon them, and that for obvious reasons they were unable to participate in the privileges of the society. The different portions of the State were at that time far less accessible to one another than at present. It was a much more difficult matter for a member to attend the meeting of the society, or to avail himself of the advantages of the library which it then possessed. As the meetings were held in Boston, and the funds and library were also there, it was evident that there was a growing feeling of discontent in a section of medical activity at the western end of the State, forgetting that Boston is nearly the geographical centre of the State, and in accessibility quite so, and this eventually found expression in the presentation of a memorial to the Legislature in 1831. No legislative action having been taken, it was finally brought up in a memorial to the society in 1848. The proposition of Dr. H. H. Childs and others contemplated that the State society should be constituted by delegates annually chosen by the county associations agreeably to the principle adopted in most of the States, thus making the basis of the society local or county associations. The petitioners claimed, in urging the measure, that the objects for which the society was first brought into existence had been completely overturned, a license being no longer required for the practice of medicine; no laws of the State or of the society were now of avail in guarding the entrance of the profession. In order to obtain such united action from the profession as could best protect and advance its interests a new plan should be devised, which would bring in a good many respectable men who were not members. The plan which was to smooth out all these difficulties was somewhat vaguely stated as "associated union."⁷ The majority report of the committee to whom this whole matter had been referred was presented to the Councilors by Dr. Pierson, of Salem,⁸ and showed clearly that the simple and efficient plan of the society had accomplished all that was ever intended by its organization in 1803; that it would be unwise to desert a system which had worked well for half a century; that it was regarded by physicians in other States and countries as a most desirable model of medical organization; and that nowhere in our country, if in any other, could be pointed out a more respectable body of practitioners, or one more highly estimated by the community. Experience since that time has amply justified the views expressed by the committee, and the society now presents an organiza-

¹ Act of 1803, section 3.

² Although the Censors had power to admit, the "letters testimonial" must have upon them the seal of the society and the signature of the president and secretary. Act of 1803.

³ About the same time the law allowing none but members to collect fees by legal process was repealed, a feeling existing in the society that such a special law worked to the detriment of the profession.

⁴ Boston Medical and Surgical Journal, vol. vi, new series, p. 311.

⁵ Discussion on having arisen of the right of the districts to send delegates to the American Medical Association, it was decided that the Councilors should be restricted not to have the society represented by delegates, but in 1852 it was decided that the Councilors should be elected by district societies must be signed by the president of the society, and the general society, and that the delegates be elected by the district societies.

⁶ Boston Medical and Surgical Journal, vol. ix, new series, p. 19, District Societies, Their Purpose, Powers, and Limitations.

⁷ M. M. S. Comm., vol. vii, p. 150, Appendix.

⁸ M. M. S. Comm., vol. vii, Appendix, p. 112. The committee consisted of two from each district society, and two from each county or part of a county in which no society had been formed; in all 32 members. The majority stood 20 to 8. It is interesting to note both in this and a previous report (vol. v., Appendix, p. 26) the stress laid upon the importance of maintaining a high and uniform standard of qualifications demanded of the candidates, which it was claimed was the chief means by which the harmony of the profession and the security of the public against unqualified practitioners were promoted. And again it was expressly stated that "the primary objects of the society are to effect a system of adequate and uniform education, and to elevate the standard," etc.

tion less cumbrous in form and in better working order, probably, than any other in the world.

It was at first supposed that the society would become a scientific body, which could discuss and diffuse medical information and improvements, and take rank among the institutions of learning and science.¹ Later, when it embraced the whole profession, the professional and scientific work was in a great degree delegated to the districts, and the general society became more especially a regulator, in conjunction with the State, of the practice of medicine, although at the annual meetings the amount of professional work is yearly increasing, and the society encourages original work on the part of members by the offer of annual prizes. Its most distinctive feature has always been the establishment of an educational standard, and in this it was aided by the government to protect the public against the introduction of improper persons to the practice of medicine. It should be distinctly understood that it was in no sense intended for the mutual protection of physicians, for individual practitioners can get on very well without the society, and the number of those whose incomes are encroached upon by irregulars is exceedingly small.² Its objects were effected first by the diffusion of medical knowledge among physicians. Prescribed courses of study³ were laid down for those who proposed to undergo the examination of the Censors. The society was, in fact, equivalent to a medical school,⁴ and at the time Harvard began to issue medical degrees the society protested against this supposed encroachment upon its privileges. The medical literature of the day was made available to members. The first Pharmacopœia published in this country was prepared for their use, and the society had no small share in forming the first Pharmacopœia of the United States. To the community it lent its valuable aid from time to time, as occasion required it. Questions of great importance were investigated by its committees, from whom many valuable reports emanated. A striking illustration of this kind of work is afforded in volume I. of the Communications, where we find an elaborate report on vaccination, read at the annual meeting, June 1, 1808. The almost complete immunity of the city from small-pox for nearly a third of a century following shows how faithfully the profession of that day performed its task. During epidemics of spotted

fever and cholera the activity of the society was conspicuously displayed. Its salutary influence was exerted in behalf of the law to encourage the study of anatomy, this State being the first to set the example of such enlightened legislation. Among the latest achievements is the abolition of the antiquated coroner system and the substitution of the medical examiner, whose important duties are throughout the State performed by members of the society, who have lately formed themselves into an association for the purpose of medico-legal studies. It was under the shadow of the society's wing that the first Board of Health in the United States was organized. And last, but not least, the great boon of anæsthesia was given to the world through the agency of its members. The new code of ethics prepared last year by a committee of the Councilors should not be overlooked. It will undoubtedly serve as a model for all future codes, and has been most favorably commented upon throughout this country and in Europe.⁵

I will now call your attention to a few typical examples of national medical associations, and to certain of our State societies whose organizations present peculiarities worthy of study.

For a number of years medical societies assembled in various parts of Europe, Switzerland being the first to hold a meeting of medical men. France and England followed her example. Italy had a gathering of physicians as early as 1839 at Pisa. It was at the annual meeting of the French Medical Congress at Bordeaux, in 1865, that it was proposed to hold an International Congress at Paris during the great exhibition of 1867. Professor Brouillard, the president of the Congress at Bordeaux, was authorized on his return to Paris to organize an executive committee, to whom the preparation of the coming meeting should be intrusted. It was intended that these gatherings should be purely scientific in character, and that there should be no official recognition by the schools or government; that they should last two weeks, and be held biennially. Foreign nations were invited to join, and their representatives were received at Paris as guests, the expenses of the meeting being borne by the French members solely. Since that time a fee has been usually demanded from each member. The preparations for each meeting are perhaps more elaborate than those of any other association, each country vying with the others in the perfection of its arrangements. Circulars are first freely distributed by the committee some eighteen months in advance, and the coöperation of the journals and societies requested. Several subjects in the earlier meetings of the Congress were selected for discussion, and were printed with an outline of the general character of the discussion it was intended to have. These occupied the

¹ Comm. M. M. S., vol. vii., Appendix, page 149.

² In this spirit are framed the laws in relation to consultations with irregular practitioners, which is regarded by a portion of the public as so illiberal. A report of the committee on the infractions of by-laws (vol. vi., Appendix, p. 10) states: "There are many who affect to think, and there are perhaps a few who actually believe, that these laws are made for the benefit of the profession, when, in truth, as the least reflection will show, their sole purpose is to promote the good of the community, — to guard the public against ignorant, designing, and unprincipled pretenders. . . . Would it be right, by consulting with such individuals, to declare to the world, as we certainly do, that we believe them to be well educated, when, to say the least, we have no evidence of the fact? Who has a right to complain of our course? Not our fellow citizens, for they can employ whom they please; and the practitioners who will not conform to our rules as to a proper course of study cannot blame us if we will not receive them as associates and fellow-laborers."

³ "That it shall be the duty of the society effectually to answer the designs of their institution from time to time; to describe and point out such a medical instruction or education as they shall judge requisite for candidates," etc. (Acts of 1803, sec. 1.) Lists of desirable medical works are frequently seen in the publications of the society.

⁴ Israel Atherton, October, 1789, recommends five years of study to those who have not received a collegiate education. A thorough knowledge of Greek and Latin was thought necessary by Nathaniel Coffin. In a report by a committee, Cotton Tufts, chairman, June 6, 1786, it appears that preliminary requirements were expected of a pupil previous to his instruction by a physician.

⁵ Dr. S. E. Chaillé, of New Orleans, in a paper read before the American Medical Association, speaks thus of our society: "It manifests its appreciation of the *mens sana in corpore sano* by expending annually about \$1800 on dinners, cigars, etc., and some \$2300 on the publication of mental food. . . . In no less than six particulars the influence of this society on state medicine deserves special attention. Massachusetts is surpassed by no other State in the variety and excellence of its public institutions for the sick and infirm. The Massachusetts General Hospital has probably no equal in this country. The Harvard Medical College has been among the very first of such institutions to establish a three years' graded course, and is in all other respects one of the best medical colleges in the United States. . . . Massachusetts has the most satisfactory, however imperfect, registration of vital statistics of any State in the Union. . . . To the Massachusetts Medical Society is also due the greatest triumph yet accomplished in American medical jurisprudence, — a triumph which on this subject places Massachusetts in advance of every English-speaking people."

day-time at the Paris meeting, while the evenings were given up to miscellaneous papers and discussions.

The first day opened with communications on the Pathological and Physiological Anatomy of Tubercle. Other papers read at this meeting were, On the Influences of Climate, Race, and Condition of Life on Menstruation in Different Countries; The Accidents which cause Death after Surgical Operations; Prophylactic Measures to prevent the Propagation of Venereal Diseases. It was found that the difference of language was a great obstacle to the success of the meetings, and that the formal discussions were lengthy and tedious, many of the papers being read for the authors. The attractions of the city and the exhibition detracted largely from those of the Congress. The attendance was large; there was a fair number of celebrities, and all countries were represented.

The second medical olympiad, as it was termed by Professor Bronnillard, was held in Florence, in 1869, Professor Salvator being the presiding officer. The general plan of the meeting was similar to that held at Paris. The chief subjects of discussion were, Marsh Miasm; The Therapeutics of Cancer; The Treatment of Gun-Shot Wounds; Hygiene of Hospitals; The Influence of Railways on the Health of Man; The Conditions which favor the Production of Epidemics in Large Cities; The Rights and Duties of Medical Men in Relation to the Government and the Reforms which may reasonably be expected.

The third meeting was held in Vienna, in 1873, at the time of the great exhibition in that city, with the venerable Rokitsansky as its president. The subjects discussed included: Vaccination, Syphilis and Prostitution, Cholera and Quarantine, Freedom of Practice in all Countries for Qualified Men, Hygiene of Large Towns. A universal Pharmacopœia was proposed, and was further discussed at the next meeting in Brussels, without any definite plan having been arrived at. This Congress does not seem to have been so successful. There were about two hundred members, but the attendance was not satisfactory, the attractions of the exhibition being great, and especially of a very fine exhibit of military surgery. The physicians of Vienna do not appear to have attempted a publication of the proceedings, which came out in abstract three years later, under the auspices of their successors.

Brussels entertained the Congress in 1875. Dr. Henricke, its president, opened the proceedings in the presence of the king. At this Congress the work was for the first time handed over to "sections;" each department presenting questions to be heard and for debate. There was a general meeting at midday, and in the afternoon the various sections held their sessions, at which a large amount of work appears to have been accomplished. This plan of organization has been retained since.

The next year being the date of our centennial celebration an extra (but apparently unrecognized)¹ session was held in Philadelphia. I need not remind you how ably the committee having the work in charge carried out their programme. Although there were but few delegates from Continental Europe, Great

Britain furnished a large number of representatives, with whose names and writings we are all familiar. With the venerable and distinguished Dr. Gross as president, and such men as Lister, Tufnell, Barnes, and Adams to participate in the debates, the meetings could hardly fail to prove most interesting.

In 1877 the Congress met at Geneva, under the presidency of Dr. C. Vogt, and was largely attended. There were numerous agreeable social features, which the picturesque locality made additionally attractive. The volume of reports is by far the most elaborate, there being also a number of very fine illustrations. There was an exhibition of instruments.

The meeting at Amsterdam, in 1879, was notable for the attendance of many scientific men of eminence. Donders was its president, Virchow was among the members, and one of the general meetings was made memorable by a sort of ovation to Lister. The social features, as usual in Continental towns, were an attractive feature.

The next meeting of the Congress is to be held this summer in London, and English physicians have certainly thus far left nothing undone to make it the most brilliant of the series. Work began over a year ago, circulars being freely distributed to all journals and societies. In this way coöperation has been obtained from foreign countries on all sides, and the organization of the various sections and the preparation of the work have been greatly facilitated. The session will open August 2d, and continue through August 9th. All legally qualified practitioners will be received on the payment of one guinea; membership will entitle one to a copy of the Transactions. It has been decided not to admit female physicians to the meetings of the Congress, but ladies will be invited to attend the social gatherings. Arrangements have been made to hold a medical exhibition at the South Kensington Museum, on a scale which has never before been attempted; it will be opened a fortnight before the meeting of the Congress.

The work has been divided up among no less than fifteen sections, which will occupy the mornings, and in the afternoon there will be a general meeting, when addresses by Huxley, Volkmann, Billings, and others, and communications of special interest, will be listened to. This and the meeting of the British Medical Association in the Isle of Wight, this summer, will prove a great attraction to American physicians.

The organization of the International Congress is of a very simple character, each meeting being completely independent of its predecessor.

The British Medical Association was founded in 1832, by Sir Charles Hastings, of Worcester. It was designed by the founder to remove the disadvantages under which provincial medical practitioners labored, owing to their isolation and want of coöperation. It is a scientific, a benevolent, and an ethico-medico-political association.² Its objects are attained by means of periodical meetings, by the publication of a weekly journal, and occasionally of transactions and other papers, and by the appropriation of certain sums of money for the promotion of the medical and allied sciences. It was at first a purely local association, but gradually extended so as to include London, Scotland, and Ireland. In 1874, the association was incorporated under the Board of Trade, in accordance with the

¹ The Congress at Philadelphia found that the meeting at Paris, after a single session, had so few of its members that there would be no larger than the subsequent price of meeting in Europe would be gained by its termination. It was also maintained, but the Congress was held peacefully, and Switzerland was accordingly appointed as the next point of meeting.

² Carmichael Prize Essay for 1879, Walter Rivington. London: Longmans & Co.

"Companies Act of 1867." The governing body is a board of directors, called the committee of council, which is composed of twenty members, elected by the council, and includes certain officers, who are *ex officio* members. The council consists of the president and other officers and representatives, elected by the various branches of the association, each branch electing one for every twenty, together with an honorary secretary. In addition to its duty of electing the committee of council it prepares an annual report of the state and proceedings of the association, proposes the place of meeting for each year, and nominates a president. Practically, however, it has little power, being generally satisfied with registering the decrees and nominations of the committee of council, which has complete control, the management of the affairs of the association being thus kept in the hands of a few men. The number of branches of the association is between thirty and forty. They embrace 7500 members, being one third of the registered members of the profession in the United Kingdom. At the annual meetings addresses are delivered by the president and the presiding officers of sections, when discussions on special subjects take place. There are sections of medicine, of surgery, of obstetric medicine, of public health, and of physiology. Committees are appointed at the annual meeting to carry out the wishes of the association and advance professional interests. These are the medical reform committee, the parliamentary bills committee, and the scientific grants committee. The last was appointed in 1874, to distribute the £300 annually voted by the association to forward original research. The second committee was appointed in 1863, and has rendered valuable service by considering all bills introduced into Parliament in any wise affecting the interests of the profession or touching the public health; amendments suggested by the committee are often adopted by the government. It also watches over the interests of the medical departments of the army and navy and the marine service.¹

The medical reform committee was appointed in 1852, and has for its special duty the advocacy of improvements in the law regulating the practice of medicine; and in order to understand the attitude of the association towards the question it will be necessary briefly to allude to the license law, or, as it is termed, "registration," in the United Kingdom. This system is supervised by a body known as the General Medical Council, composed of representatives from the different examining bodies throughout Great Britain and Ireland, and several members appointed by the Crown.² These are the bodies whose diplomas are recognized by the council for registration, and no man can be a legal practitioner unless he is entitled to be placed on the medical register. It must be remembered that these licensing bodies, seventeen, or as is more lately stated nineteen, in number, such as the Royal College of Physicians of London, of Edinburgh, of Ireland, and the universities, are not necessarily charged with the teaching of medicine, which function is performed by the medical schools, of which there are in London alone a large number, attached to the several hospitals. Registration is not made compulsory, nor can any penal-

ties be inflicted upon an unregistered person who, having obtained a diploma, practices in accordance with such qualification; but without being upon the register no one can recover fees in a court of law, nor hold a government position, nor sign medical certificates; he is wholly shut out from official medicine. Those who practice without a diploma can be prosecuted in case they assume a title recognized on the register, and are then liable to a fine of twenty pounds for each offense. The eclectic and homeopathic practitioners are not sufficiently numerous or influential to secure a representative in the council; no such effort has, at all events, been made.

Although all the diploma-granting institutions are thus united under one controlling body which secures a minimum of requirements, the standard of excellence is a very varying one, and attempts have been made to form an examining board which would represent all these bodies, and also to institute a state diploma which should be compulsory for all students before their names could be placed upon the register, but as yet without success. The constitution of the council is apparently not satisfactory to the profession, as both the association and the prominent journals have favored a reorganization upon a basis which would represent the profession at large, rather than the diploma-granting bodies which it is intended to control.

It will thus be seen that the organization of the association is such that it is able to exert a great deal of influence, not only in matters pertaining to the welfare of the profession itself, but also in legislation bearing upon state medicine.

There are several prizes: the Hastings medal; two triennial prizes, being the interest on certain sums presented by members of the association; and a medal for "distinguished merit," awarded to any member of the profession for heroic conduct or special services to the association.

The management of the British Medical Benevolent Fund, which has an annual income of over three thousand dollars, has been in the hands of the association since 1835.

The special feature of the association, to which is due in a great degree its brilliant success, is the *British Medical Journal*. This weekly periodical had its origin in the volumes of Transactions, nineteen of which have been published in twenty-one years. It was first started in 1840 as *The Provincial Medical and Surgical Journal*. In 1844 it became the official journal of the association, and was at first controlled by a committee. This was not a very successful arrangement, and the journal was transferred to Worcester, where it was issued once a fortnight. In 1853 it was again taken to London, and published as the *Association Medical Journal*, under the editorship of Dr. John Rose Cormack. In 1856 the present title was adopted, and ten years later Mr. Ernest Hart, the present editor, assumed charge. Under his able direction the circulation, and with it the membership of the association, increased from twenty-five hundred to over seventy-five hundred, and additions to this number are constantly being made. The magical effect of the influence of the journal upon the association is graphically described by Dr. Sayre in his address delivered, last June, before the American Medical Association, wherein he advocated a similar experiment in this country. The proceedings of the association appear promptly; every address or article, with the discus-

¹ Through the influence of the committee numerous acts have passed Parliament dating back to 1843, which have established an efficient system of public hygiene, with 15,000 sanitary districts and the requisite number of sanitary officers.

² In the Medical Directory for 1874 seventeen members represent these bodies, and five are appointed by the government.

sions to which they have given rise, appear in the pages of the journal; and as work is going on the year round there is a constant supply of material, and the interest is kept alive. As Dr. Sayre truly remarks, "Certainly in this way the British Medical Association has become the most powerful medical association in the world."¹

(To be continued.)

THE EARLY DIAGNOSIS OF PROGRESSIVE PARALYSIS OF THE INSANE.²

BY CHAS. F. FOLSOM, M. D.

A CAREFUL study of progressive paralysis or general paralysis of the insane embraces the whole range of mental pathology; it includes almost every perversion of the intellectual faculties, every moral obliquity known in the various forms of insanity, under the influence of a single disease, and, so far as we know, with scarcely varying pathological changes in the structure of the different parts of the brain, such unlike symptoms are produced that if grouped together there is no type of mental disease the prominent points in which would not be represented. There may be simple melancholia, hypochondria, suicidal or homicidal impulse, mania of all degrees, from the simple type to the most violent delirium, monomania, stupor, dementia, and finally gradual mental decay without other prominent symptoms—all this with such definite and well-marked physical indications successively of slightly imperfect action, ataxia, and paralysis that no two cases can be said in the latter respects to be essentially unlike.

A knowledge of the relation of pathological changes in the brain to perversion or loss of mental function in general paralysis would imply a full understanding of the intimate sources of intellectual action. The fact that with such uniform morbid anatomy of the parts there is found such a vast range of entirely differing affections of the mind indicates that at present we know next to nothing of the real pathology of insanity.

One may expect to meet the disease most commonly in men of the lower classes, next in order in men of the more favored classes, then among women of the low orders, and very seldom among the upper circles of women. It is calculated that one in thirty of all persons reaching the age of twenty may be expected to become insane in the older States; from one in six to one in twenty of insane men will be general paralytics, and that disease occurs six to eight times as seldom in females as in males. It is much less prevalent in new and fresh places than where population is centralized; it is more common, for instance, in our eastern cities than in those of the West, and least often met in the farming districts of our new States. Its frequency has undoubtedly become more and more marked during the last twenty-five years.

General paralysis is to a less extent directly hereditary than any other form of insanity. While it is to be looked for chiefly in robust men in active life, between the ages of thirty and fifty, now and then it is found under twenty or over sixty, and more rarely still in weak, debilitated persons. Its causes are thought to be, for the most part, in exhaustion from prolonged

strain, mental or physical, or both. When from mental strain, the overtaxing of the system is very likely to have begun in early youth, especially if too little sleep and inadequate food have also combined to lower the tone of the system. That purely intellectual overwork is not the chief source of general paralysis is evident from the fact that the disease is not most prevalent among brain workers. It is a disease of physical degeneration rather than of advanced civilization. Sexual excess, especially if added to over-indulgence in alcohol, begun in early life and prolonged, with underfeeding, seems to me one of the most common causes of general paralysis; and it should be borne in mind that sexual excess is most likely in married people, with whom the temptation and opportunity are more common than in single life. Syphilis, so far as I am able to judge, is rather an accidental complication of general paralysis than a necessary feature in its causation. Thoroughly licentious persons are more apt to have both syphilis and general paralysis than those who are temperate in all things. Given a boy who makes his way in life against poverty and opportunity by overwork, underfeeding, and hardship from his earliest years, who keeps up the strain in later life to gain by his unaided efforts an ambitious position, and at thirty or forty begins to live in unaccustomed luxury, indulgence, and excess, if he inherit an unstable cerebral organization, or anything but a vigorous constitution, and one has a typical case for the possible development of general paralysis. Some stress has been laid upon the importance of what has been called an emotional shock in the production of the disease, but I doubt whether the intense emotion does more than render the accustomed self-control impossible, and thus conspicuously show in a marked manner symptoms which previously were so slight as not to have been noticed.

Unlike the phenomena of many other forms of insanity, those of general paralysis depend upon morbid conditions, which are, as a rule, slow in manifesting themselves. There is commonly a long first stage of the disease, which lasts for a year or two, or even longer, when the only definite symptoms are very nearly the same as those in some of the forms of simple prostration and cerebral exhaustion. There is apt to be more or less headache followed by a certain slight blunting of the moral sense and perception of the proprieties of life, decreased capacity of prolonged or sustained attention, more or less irritability, an occasional outbreak of temper from trivial causes, some excitement of the emotions more than is characteristic, with perhaps melancholia, hypochondria, or even no more than a rather disagreeable feeling of self-distrust. There is also the slightest approach to hesitation in speech, when wearied, which is neither ataxic nor paralytic, and which depends simply upon the inability of the brain to act with its usual rapidity, promptness, and force. There may be even a little unsteadiness in the handwriting, particularly if the individual be one of naturally emotional temperament. Now and then there is a transient feeling of lightness about the head hardly to be called dizziness, but occasionally amounting to epileptiform attacks, which may be analogous to the transient passionate outbreaks that are observed, and as inexplicable to the friends of the patient as they are unnatural to him. All these indications may be present, and the forgetfulness of the nicer proprieties of life may be quite marked, while the judgment

¹ *Lancet*, vi. Jan. 10, 1879, p. 15, and 1879, p. 15.
² Read before the Suffolk District Medical Society.

and mental acuteness remain without noticeable change. Up to this point there is no positive way of differentiating in diagnosis general paralysis of the insane from simple cerebral exhaustion, although the latter should not fail to be suspected. In the case of the former, however, the chances are that the body would be well enough nourished, the sleep pretty good, the appetite fair, and that there would be no functional disturbance of the heart, neuralgia, or excessive unsteadiness of the nervous system, all of which would be expected where no organic disease is present.

This stage may last for several months, possibly a year or more; and the attention of the friends may be called for the first time to an inaptitude for work, which they cannot explain, or to an actual offense against the customs of society, decency, or the laws. As the disease advances, the melancholy or lack of self-confidence disappears; instead of feeling that there is something the matter with him, the patient begins to have an unusual satisfaction in his condition and prospects — says he was never better in his life. This is the rule, although the depression sometimes lasts to the end. If there has been, as may be expected, exaggerated sexual inclination, it persists for a while; otherwise it makes its appearance, generally to be soon lost again and reappears in the later stages; there is often an increased disposition to the frequent excessive use of alcohol. The occasional light feeling in the head is apt to increase to vertigo or epileptiform attacks, which latter may be so prominent as to give rise to the diagnosis of epilepsy. There is a seeming loss of memory, which really consists chiefly in a diminished power of attention, and in failure rather than inability to fix recent events in the mind. There is a marked weakness in the intellect which shows itself in the unusual unwisdom of plans proposed, the readiness with which cherished objects can by tact be driven out of the mind, and an almost childish willingness to be led by a practiced hand. There is commonly an extraordinary feeling of comfort and contentment, which now and then amounts to a violent sense of personal power, but is oftener one of most expansive egoism, without dangerous proclivities, although suicidal and homicidal or other violent impulses now and then occur. The emotional feature is, as a rule, very prominent. These psychical symptoms may be varied, as already stated, still so as to present almost any of the characteristics of the various forms of insanity; and a positive diagnosis may for a time be impossible.

The purely physical symptoms are more pronounced, and as soon as they are once recognized beyond a doubt, the unfortunate patient's death-warrant is as good as signed. A few recoveries have been reported, very likely due to erroneous diagnosis. The men recorded as having got well under the use of Calabar bean, in one of the English hospitals, are long since dead, and illustrate the error which occurs of failure to discriminate between a remission and a recovery. Quite early in general paralysis, one may expect to find oftener than not a narrowing of the pupils of the eye, more commonly of one eye than of both, and more frequently of the left than of the right; but this is not an unvarying nor a diagnostic sign. The slowness or hesitancy in the action of the finer muscles, due to cerebral sluggishness, is succeeded by ataxia, which is commonly first observed in the muscles of articulation, chiefly of the lips and tongue. This can be detected quite easily in long sentences and is a much later symptom than

the fine fibrillar tremor which so early appears in the tongue and upper lip. If the progress of the disease is rapid, the muscular tremor may amount to marked spasm and incoördination, so as even to produce stammering or stumbling in speech, especially in the pronunciation of several long words together. Indeed, a markedly defective articulation or "thick speech" may be the first symptoms observed by the patient or his friends. The handwriting becomes unsteady and tremulous; and there may or may not be omissions of letters, syllables, or whole words in writing.

The ophthalmoscope gives no assistance in diagnosis except possibly sometimes to differentiate the disease from suspected tumor of the brain, while thus far the sphygmographic tracings have offered nothing distinctive or definite in the early stages. The morning temperature is nearly normal, where the progress of the disease is slow, and is elevated above the normal in pretty uniform ratio to the rapidity of the progress of the pathological changes in the brain; it rises also in a corresponding manner from a half degree to a degree and a half at night.

Very rarely, indeed, progressive paralysis of the insane runs its complete course with extreme rapidity, the whole duration of the disease, from the appearance of the first slight indications until death, being only two months or even less. In the only case of this kind which I have had the opportunity to observe, the first symptom which I could detect, on the most rigid scrutiny of the friends of the patient, was an extraordinary exhilaration after drinking an amount of wine which was customary and which had never before produced any noticeable effect. From that time till death only seven weeks elapsed. In this case the temperature was at first a full degree below the normal, and the duskiness, almost suggesting lividity, of the skin marked a striking failure in the innervation and circulation of the system.

The weakness or shuffling in the gait in uncomplicated general paralysis is so late a symptom that it seldom appears until long after the diagnosis may be settled upon other indications. It can best be detected early by the attempt at some such complicated movement as the right-about-face of the military drill, or in walking rapidly up and down stairs with high steps; and this may be quite noticeable when the patient can walk, run, dance, stand with his eyes shut, rise up in a chair, etc., tolerably well. Not seldom, however, the ordinary history of posterior spinal sclerosis is associated with general paralysis, and then the symptoms of progressive locomotor ataxia are early detected: this affection of the gait is quite different from the uncertain step due to cerebral disease and succeeding descending degeneration of the lateral columns of the spinal cord, as observed in pure general paralysis. Indeed, the tabic symptoms may be the sole indications of disease for several years before the characteristic features of general paralysis of the insane appear; and I saw a year ago a case in which one of the possible errors of diagnosis seemed natural, namely, that the malady was bulbar palsy, although on full investigation it proved to be clearly general paralysis. There is present now and then cutaneous hyperæsthesia, either slight, moderate, or excessive, but more commonly a certain degree of anæsthesia is found. There is almost always increased muscular tension, indicated by a decidedly increased knee phenomenon.

It is not my purpose to occupy your time with the

pathology, clinical history, and full account of the later stages of paralysis, dementia, and death, which are sure to follow in a shorter or longer time the first positive signs of general paralysis of the insane. It is worth while to call attention to the importance and not infrequency of the disease; to show that its early symptoms may easily be misinterpreted, and to indicate, in passing, that the complaints not very uncommon among men who have been exhausted by prolonged strain, and who simply need rest to become well, not seldom so resemble the early features of general paralysis that a positive diagnosis must be deferred to await the results of time and treatment. Whether the pathological changes in the two conditions are so nearly identical as to allow of our hope that both may be cured by early treatment, the future must decide.

THE PRESENTATION OF THE PORTRAIT OF DR. J. B. S. JACKSON TO THE BOSTON MEDICAL LIBRARY ASSOCIATION.¹

DR. O. W. HOLMES'S REPLY.

MR. PRESIDENT AND GENTLEMEN OF THE SOCIETY FOR MEDICAL IMPROVEMENT. — In the name of the Boston Medical Library Association I receive this portrait of our late honored and beloved friend, to be faithfully guarded and reverently cared for, so long as it shall remain in the keeping of the Association. In these well-remembered features we see the outward semblance of a character which we have long looked upon as one of the truest and purest that ever adorned the ranks of the medical profession.

Our late associate had some right of inheritance in the virtues which most distinguish the physician. Dr. James Jackson, whose son was taken away in the freshness of his early promise, found no unworthy representative in the nephew whose memory is in all our minds and hearts. Their course of life differed widely, yet they had many of their finest traits in common. The elder Dr. Jackson was born for a practitioner. There is an art of healing as well as a science of medicine. Dr. James Jackson admirably represented the former. The bedside was his place of study; the stethoscope performed his living autopsies; his laboratory was the patient's organism; his microscope sagacious insight; his thermometer the skillful touch of long experience; and better than all the rest he carried with him the *biometer* of a *visus eruditus*, that well-trained faculty, above all others, which measures the life movement and the forces behind it, and knows when and how to check, to urge, to sustain it in its efforts, or to change their direction.

To this task our friend could not be said to have devoted his main energy. He practised to some extent, but he did not surrender himself to the exacting demands of professional labor in a crowded city. Had he attempted this one more wise practitioner would have been added to the many whom we have enrolled upon our record. But how much would have been lost to the science which helps to make whole schools

of wise practitioners! How much to that spirit of harmony and union in the profession, for which our city has long been distinguished! For the pursuit of *science*, that is of true knowledge, is one of the strongest cements that bind men together. Nature enlarges, illuminates, ennobles the minds of the votaries who listen to her oracles, and lifts them above the region of personal feuds and petty jealousies.

Dr. Jackson, the pathologist — morbid anatomist, he would have modestly called himself — was an enthusiast in the study of Nature in one of her least attractive aspects, but one in which she reveals herself as in no other. Age could not subdue the boy-like vivacity with which he followed the scent of a pathological fact, under conditions to most persons the reverse of alluring. His senses were very delicate; he loved fair sights and sweet harmonies, and the fragrance of garden-walks, but he would leave the landscape, the concert-room, the flower-garden, to glean one little fact left to be gathered in the field which had been reaped by successive generations of pathologists.

Science is never false, but scientific men have not, it must be owned, always been truthful. Who was ever more absolutely to be depended upon as incapable of saying the thing that was not, than he whose features live upon this canvas? I would not quote irreverently the question of the Roman governor, and the anagram in which it has been answered, but truth is sacred alike whether the lips that utter it are human or divine.

"*Quid est veritas?*" said jesting Pilate,"

and ingenuity has transposed the letters to the answer,

"*Est vir qui adest.*"

So would those who best know our friend have told him to answer if he had been upon the witness-stand and Pilate's question had been asked him.

This is not the occasion for telling the long story of Dr. Jackson's life and labors. Nor is this the audience that needs to be reminded of them. I cannot help recalling the noble words of Ulysses in the *Iliad*: —

Tydidēs, praise me not too much, nor blame.

Thou speak'st to Argives, all these things who know.

More especially is it needless to discourse at length to the members of the Society for Medical Improvement on what they owe to the labors of Dr. Jackson. I can speak from my own knowledge of this society in its earlier period, for I was then a constant attendant at its meetings, and have an impression that I acted for a time as its secretary. I recall the days in which, with at least as much truth as there was in Louis Fourteenth's saying he was the throne, it might have been said that Dr. Jackson was the Society. He was its support, its main pillar, untrifling and untrifled as a marble caryatid — say, rather, its vertebral centre, around which all its limbs and organs were disposed. Did others fail to appear, he was always present; were others silent from lack of material for discourse, he was always ready with the story of some new and interesting case; had others brought no specimen to show, he was sure to unwrap some embryonic *jeu d'esprit* of Nature, or some fragment of unenviable personal property not mentioned in the late owner's will or codicils. He has left the memory of all this in the two imperishable fluids, ink and alcohol; in his minute and thoroughly trustworthy records, partially reproduced in his two monumental printed catalogues, and in the jars

¹ In the issues of the *JOURNAL* for May 26th and June 24, pages 460 and 544 respectively, appeared the report of the committee appointed to prepare a portrait of Dr. J. B. S. Jackson for the Boston Society for Medical Improvement, and a report of the presentation of the portrait to the Society by the Boston Medical Library Association. The secretary, Dr. O. W. Holmes, accepting the offer for the Library Association, regretted that he could not appear in these reports, and we are glad to be able to present them to our readers now. — EDITOR.

where the liquid which destroys the organs of the living confers a kind of immortality on the viscera of the dead.

Dr. Jackson lived in and to the close of that era of pathological anatomy, which began with Morgagni and finished with the labors of Louis and his contemporaries, to give place, or rather to yield precedence, to the dominant study of pathological histology. He would never meddle with the microscope; he was always contented with his natural lenses of ten inches of focal distance. And thus, whatever he lost, he escaped one of the not infrequent effects of over-reliance upon the instrument to which we are under such almost infinite obligations, but which is breeding a generation of intellectual myopes as one of its natural products. His honest eyes were naked and not ashamed, even in the days of Tolles and Beek and Hartnack. But what he saw with those honest eyes was seen clearly, and what he told was related faithfully. There is nothing more genuine in all medical literature than the records he has left of what he observed and has bequeathed to those who come after him.

We will give his portrait a conspicuous place upon these walls, and by and by, those who come after us will replace it upon the walls of that larger edifice which will, in the fullness of time, spread its roof over these accumulating stores of knowledge. No companionship it will ever find will be too good for it. Call up in counterfeit-presentment the great masters of every age and every land: the Father of Medicine from his island in the Ægean; the friend and physician of Marcus Aurelius from his Mysian sepulchre; the restorer of anatomy from the rock where he perished by shipwreck; the great English practitioner who dared to bring common sense to the bedside where tradition and superstition had long reigned paramount; the discoverers, the inventors, the scholars who have built up medical science and art; Paré and Harvey, and Jenner, Hunter, and Haller, Bichat and Louis; summon the men illustrious in our friend's chosen specialty, Morgagni and Cruveilhier and Rokitsansky; nor forget those who have honored our own country, our own New England, our own Boston, where inoculation was first introduced and vaccination first practised on these Western shores; where etherization first came to lift the curse of Eden from Christendom; among all these not one pursued his branch of science with more enduring enthusiasm, with more single-hearted determination to learn what Nature had to teach him, or with a more modest estimate of his own achievements; not one has left a memory embalmed in more grateful and kindly recollections than JOHN BARNARD SWETT JACKSON, whose face we look upon no more, save as Art has preserved it for us and our posterity.

Therapeutic Memoranda.

THE USE OF OLIVE OIL AS AN EXTERNAL APPLICATION IN DISEASES OF THE CHEST.

BY W. THORNTON PARKER, M. D., PLYMOUTH, MASS.

WHILE a student in Professor von Gieth's Physical Diagnosis Class in the Munich General Hospital I frequently had occasion to notice the use of olive oil as an external application in diseases of the chest. This, if I remember rightly, Professor Gieth preferred to all other external applications, such as Indian meal, cotton

wadding, flannel, or rubber jackets. Of course I am not considering the stage of those cases where counter-irritation would be necessary.

Professor Gieth used a double fold of common cotton cloth, large enough to completely surround the body, the cloth he thoroughly saturated with warm olive oil. I think the Professor considered this generally sufficient without the addition of flannel. I have never seen this treatment recommended in any of our medical works, but in private practice very often since then I have had occasion to be grateful for this valuable suggestion, and find the use of the olive oil excellent in almost all diseases of the chest. It is certainly very agreeable to the patient, besides being, as Professor Gieth suggests, the best means at our disposal for *retaining a steady amount of heat*. The oil softens the skin and is probably more or less absorbed, which is of itself beneficial. This application is renewed from time to time as required.

The objection to the Indian-meal jacket is that it rapidly cools and is liable to wet the bed-clothing and chill the patient, thereby defeating the desired results.

I am induced to mention this treatment in the hope that those who are unfamiliar with its use may give it a trial at this season of the year, when lung diseases are so prevalent.

Reports of Societies.

ANNUAL MEETING OF THE CONNECTICUT MEDICAL SOCIETY.

THE ninetieth annual convention of the Connecticut Medical Society was held at the Common Council Chamber, City Hall, Hartford, May 25-26, 1881. The attendance was large, every section of the State being well represented. The business of the society is transacted on the first day by Fellows, so called, chosen by the eight county societies which unitedly form the State Society. These were all present except four, forty-two out of a possible forty-six; two of the absentees were in Europe; one of these was the president, so the vice-president, Dr. Deming, presided.

There was an unusual amount of business before the society and in reality two days ought to have been devoted to it; an evening session was rendered impossible also, as the society were then invited to a reception by Dr. Mann, the well-known gynecologist, formerly of New York, now a resident of Hartford.

After the usual routine business the society listened to a carefully prepared and well-studied report by Dr. G. W. Russell, of Hartford, chairman of the committee on Expert Medical Testimony, appointed the previous year. The inherent right of the accused to confront the witnesses against him was presented as a bar to any radical changes in the present system. The other obstacles could be readily overcome by changes in the statute law; for instance, the court has no power to summon experts nor have the judges except under one or two very unusual circumstances, but a law could be passed giving the court power to summon one or a council of experts, but the first objection is an insuperable one. The only progress that appeared at all possible lay in improving the character and tone of the medical profession itself, so that no reputable practitioner would sell his opinion to the highest bidder. Already the courts are beginning to discriminate between the professional witness, whose fee is conditioned

upon the amount of damages secured, and the non-partisan witness, who presents the facts in the case clearly and simply; and a skillful lawyer readily finds methods to bring into discredit the mercenary witness, whose only thought is gain. The evils of the present system, as recently exposed in our courts, were freely admitted, but the difficulties in the way of any radical change are insurmountable. The paper bore evidence of careful study, and was backed by the best legal talent in this State.

The special committee on the sale of poisons reported through their chairman, Dr. Rufus Baker, of Middletown, that the list of poisons whose sale should be recorded ought to be increased, and others should be guarded by special marks and clearly labeled "Poison." A list of the two classes was presented, and further legislation advocated. Some discussion followed both of these reports, but no resolutions concerning them were presented.

Dr. M. White, of New Haven, then read the report of the Committee on Vital Statistics, recommending that a better execution of the laws be insisted upon, but suggesting no new legislation.

This report was followed by considerable discussion by Drs. Hubbard, Cleveland, Burke, Mayer, and Chamberlain. Complaints were made that names of physicians and patients were published by local papers to the detriment of the public interest.

The discussion showed that the present laws were sufficient, for the most part, if well executed. It was a common right to consult public records, and difficult and, indeed, impossible, to deny this.

The Board of Health checked and prevented all such abuses as were brought to their notice. On motion of Dr. Burke the secretary of the State Board of Health was requested to pay special attention to these abuses, and secure, if necessary, additional legislation to prevent them.

Dr. A. M. Shaw, of Middletown, read a report on the Expediency of Lunacy Commissions, presenting a very able and exhaustive résumé of the whole subject; the history of the aims and results of such agencies on foreign countries, and in different States of our own country, was fully described and on the whole the system was commended, especially for the larger States. The paper was a general defense of the asylum system of treating insanity, and, with some reservations, endorsed the prevalent methods and plans for the treatment of insanity.

Dr. D. A. Cleveland presented a minority report dissenting almost entirely from every conclusion of the majority report; in general it was in accordance with the well-known views and methods of Dr. W. A. Hammond and his school.

As it was becoming late and much essential business required to be done, on motion of Dr. Chamberlain both the reports were laid upon the table; they were afterwards ordered to be printed, but no time being afforded for their discussion later they go to the next convention as unfinished business.

The report of the treasurer was presented, showing a healthy state of the finances of the society and an increasing amount of honesty among the members in paying their just dues. In Hartford, Middlesex, and Loudon counties there were no delinquencies, two members in Windham and two in Litchfield had neglected to pay, while in the other counties the delinquents were many. The largest income is received

from Hartford County, although that is the second in size; but there is but little difference between it and the largest,—it has one hundred and two members and New Haven one hundred and seventeen. The report shows a balance of nearly four hundred dollars in the treasury.

The nominating committee reported the following list for officers for the ensuing year, and they were all chosen unanimously. Dr. Edgerton resigned, but his resignation was not accepted; he has made a very efficient officer.

President, Dr. William Deming, of Litchfield.

Vice-President, Dr. William G. Brownson, New Canaan.

Secretary, Dr. C. W. Chamberlain, Hartford.

Treasurer, Dr. Francis D. Edgerton, Middletown.

Committee on Matters of Professional Interest in the State, Dr. W. A. M. Wainwright and Dr. S. S. Wilcox, of Hartford, Dr. G. F. Lewis, Bridgeport.

Delegates to Massachusetts Medical Society, Dr. D. A. Cleveland, Dr. M. V. B. Dunham. The report of the committee to nominate professors at York Medical Department was presented by Dr. R. S. Goodwin.

With the advice and concurrence of the President and Faculty of Yale College the following gentlemen were elected professors in the Medical Department of Yale College: Dr. F. M. Prudden, Dr. F. E. Beckwith.

Dr. Pliny Earle, of Northampton, was nominated as an honorary member; by rule this goes over until next year for action.

The reports of various standing committees were presented, and after other routine matters of business the society adjourned.

In the evening a pleasant reception was given to the members of the society by Dr. M. D. Mason, lecturer on gynecology at Yale Medical School. This was well attended, and proved a very enjoyable occasion.

The annual convention mass meeting was held Thursday at the City Hall, commencing at half past nine, A. M., President-elect Deming in the chair. The secretary's report showed a continued state of prosperity. The society now numbered four hundred and thirty. There were thirty-two new members and seven deaths; the net gain was about fifteen, taking the removals into consideration as well as the deaths. The growth of the society had been steady for the last five years; this was most marked in Fairfield County, which had increased from forty-five to seventy-one members. The report of the committee on matters of interest was then read by Dr. Wilcox. The history of epidemic diseases, as presented in the report of the State Board of Health, was commended, and a further account of the manifestations of small-pox was also given. The subject for discussion was consumption, especially with regard to its contagiousness. The general opinion was that it is contagious from person to person by long and close association, for example, occupying the same room. A paper on the Transmission of Bovine Tuberculosis to Man was expected from Dr. Cressy, but he was unavoidably absent.

Dr. Robert Dixon, of Maine, and Dr. T. W. Perry, of Rhode Island, were present as delegates, and briefly presented the greetings of their respective societies. Dr. E. C. Seguin, an honorary member, and Dr. Paul F. Mundé, of New York, were present; also Dr. A. R. Smart, of Michigan.

After the reception of delegates, reports of delegates to other societies were received.

The society then listened to an able and exhaustive essay from Dr. Seguin, the celebrated neurologist, upon the Early Indications of Epilepsy. Any attempt at analysis of this masterpiece would fail to do it justice; it must be read to be appreciated.

Dr. S. B. St. John read a very interesting essay upon Sympathetic Ophthalmia, and at the close exhibited a magnetic apparatus for removing particles of steel or iron from the eye by the power of magnetic attraction. The power of so small a magnet seemed almost incredible. An electro-magnet for the same purpose was also shown, an inferior instrument on account of the trouble from the wires.

Dr. Fleischner read an essay on Non-Pharmacological Therapeutics, in which he showed the value and power of many remedies and processes not official.

Interesting papers on The Influence of Temperature in Disease, by Dr. C. B. Newton; Treatment of the Third Stage of Abortion, by Dr. J. H. Grannis; and Treatment of Lacerations of the Cervix, by Dr. M. D. Mann, were read; the latter was discussed by Dr. Mundé and others, and elicited a great deal of interest. The society, after listening to several voluntary papers, adjourned to dinner at the United States Hotel, which proved a very pleasurable occasion.

During the session of the society there was a very fine exhibition of drugs by Parke, Davis & Co., the Trommer Malt Company, Phillips & Co., and of surgical instruments by John Reynders & Co., and S. Hernstein & Co. These attracted considerable attention. On the whole, the session was as interesting and profitable as any ever held. The papers were of unusual interest, and were much better listened to than is the rule. The next session will be held at New Haven, May, 1882.

ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY.

THE Massachusetts Medical Society, in the programme of exercises of its one hundredth annual meeting, made a decided innovation upon its time-honored practice, by the omission of all strictly scientific papers, and set before its members a variety of entertainments, which were entered upon with zest.

It did not, however, put aside entirely its professional character. If it did not attempt didactic instruction, it presented a series of object lessons, from which even the wisest of its members, who only lent his eyes, could not fail to draw some slight lessons.

The first entertainment upon the programme was the visit to the Abattoir. A special train started from the Albany depot punctually at the advertised time, carrying nearly a hundred men. The visitors were shown the various processes, and given as clear an idea as possible of the workings of this model establishment. As soon as the number of visitors to the Abattoir was known, or immediately on the starting of the special train, word was transmitted to Cambridge, where the proper number of barges were sent to Brighton, and the visitors transported to Harvard Square.

Meanwhile, in accordance with the programme, the various collections at Harvard were thrown open, and were visited by various members. It was an opportunity never before offered to the society, and they gladly availed themselves of the privileges.

At eleven o'clock precisely the oration by Dr. GREEN was delivered in the Sanders Theatre (the public lect-

ure room of the college, so recently the scene of the Greek play). This oration formed the nucleus of our last number.

At twelve o'clock exactly the lunch was served in Memorial Hall. The society was welcomed in a few graceful words by PRESIDENT ELLOR, in behalf of the corporation and professors of the University, to which Dr. WILLIAMS replied as follows:—

"Mr. President, Gentlemen of the Corporation, and Professors of the University. — In behalf of the Massachusetts Medical Society, *quoniam contra dicente*, I offer thanks for the large and graceful hospitality with which Harvard College has welcomed us. Your invitation was interpreted as a flattering token of honor and of sympathy; that it was thus intended has been most amply shown, in the manner of our reception, and, Mr. President, in your kind and courteous words.

"Many of our Fellows, recalling their early years, spent under the benignant sway of Alma Mater, mark with filial joy the evidences of her prosperity; not only in these sumptuous and convenient buildings, but in the immense increase of facilities for instruction, for study, for comfort, and for health. Others of us, coming to this ancient university for the first time, cannot but be impressed by the wealth of resources, in learning and in science, here offered for selection to their votaries; even Celestials, in shining raiment, lending their aid to the aspiring student.

"It is a privilege to visit these magnificent museums, so nobly founded and so generously endowed, which will be enduring monuments of the wisdom of their benefactors; to view the rich stores of the vast and commodious library; and to find in the splendid gymnasium the means which secure to the educated man a healthy body for the abode of a sound mind. From this hall we shall carry with us reminiscences which will remain in our hearts.

"As Fellows of the Massachusetts Medical Society, as members of the medical profession, we owe much to the college. Most of our original corporators were graduates of Harvard. Less than two years after the incorporation of the society its officers were invited to attend the public induction of the gentlemen elected as the first medical professors, and to dine, on that occasion, with the corporation and overseers in the hall. At a later period, to avoid any semblance of interference with the chartered privileges of the society, the college authorities agreed to expunge from the diploma any words implying the right to *practice* medicine; and not to examine for a degree such candidates as the censors of the society had rejected.

"It is due to the fostering care and willing coöperation of the college with the society that the standard of education in the medical school has been kept so high as to place its graduates far above the level of charlatans and pretenders.

"It is therefore most fitting that this university, and the society which to-day comes to greet its elder scientific sister, should continue in the future, as in the past, to strengthen each other's hands. The honor and welfare of the profession of medicine is committed to their joint keeping.

"Having regard to our quality as guests, you have forbore, Mr. President, to set forth, in persuasive words, the needs of the university. Nevertheless, we propose to follow the example of the apostles; and, of such as we have give we thee. The Fellows of the society have wealth of olive branches, present and prospective.

These shall we send for your acceptance; sure that they will thrive in this congenial soil; and hoping that when transplanted to the larger field of the world they will do credit to the nursery in which they were trained."

The lunch was evidently enjoyed by the members of the society, and the hall presented peculiar facilities for serving so large a number. At the close of the lunch horse-cars were in attendance to convey the visitors back to Boston, and landed them at Bowdoin Square, where were waiting a long line of stages, to which they were quickly transferred and conveyed to Rowe's Wharf, where the steamer Governor Andrew was waiting for the harbor excursion. Embarking at two o'clock, it passed first in view of the navy yard, steamed by the piers of East Boston down the harbor, along by Deer Island, by the forts and the lower light, several miles out toward Minot's. Turning about, they came part way back, took the inside route and landed at Nantasket soon after four. Here a standing lunch was served, which the sea air made doubly welcome. The music was furnished by the Cadet Band, which also played while on the boat. At half-past five they started on the return, and came alongside the wharf five minutes after the time appointed. There was much fun and singing on the trip, and the enjoyment of the sail was greatly increased by the opportunity afforded for social enjoyment and the renewal of old friendships, which was evidently appreciated by the seven hundred doctors. The only delay in the execution of the programme for the day, as originally planned, was in the arrival five minutes late at the wharf on the return. About seven hundred members of the society enjoyed the harbor excursion.

At four o'clock the adjourned meeting of the society took place.

ADJOURNED MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY IN HORTICULTURAL HALL, JUNE 7, 1881, FOUR P. M.

The meeting was called to order at four p. m., the president, DR. WILLIAMS, in the chair.

DR. GOSS read the records of the last meeting, which were accepted.

DR. WILLIAMS said that the contingency for which this meeting provided no longer existed. Therefore there was no business before it.

DR. S. CAROL said this meeting was called a year ago, and we have nothing to do with the reasons given at that time for holding the present one.

DR. CHARLES P. PUTNAM said that as the society voted at its last meeting to discuss the question of the admission of women he moved that it adjourn to eight o'clock for that purpose. Seconded.

DR. HOSMER said that the meeting was not necessary. It was unfortunate, unwise.

He would not say anything about the legality of it. He would not discuss that. It was under the circumstances unnecessary. The contingency for which this meeting was to provide had not arisen, therefore there could be no business before it. It was unfortunate, because it interfered with the harmony of the day. It had been hoped that the time might be devoted to pleasure. The adjournment seemed to him also unwise and unfair, because many members would be unable to attend. It was discourteous to Fellows because it interfered with their attendance at the reception of the president. It was discourteous to the council, which would then be in session. The council was expected

to attend to its duties, yet the meeting was to be adjourned to an hour which interfered with those duties. It was discourteous to the president, for he would have to leave his guests to be present. Dr. Hosmer, therefore, moved to adjourn. The motion was lost by a vote of twenty-one to twenty.

DR. C. P. PUTNAM said that at the last annual meeting it was moved by Dr. Bronson that the society adjourn for a particular purpose. It was well known then that this would be the centennial anniversary and that much time would be taken up in its celebration. It was moved that the discussion should be left for another year, and the society voted to have it this year. All provision for this meeting had been omitted in the programme. The officers of the society had said that they knew of no such meeting. The manner in which it had been left out was what he objected to. The president had maintained that there was no business before the society. It did not seem to him that because the question, for which Dr. Bronson's motion provided, had not been acted upon by the council, the society had, therefore, no right to discuss it. The society was paramount on such an occasion. There were cases where the society had framed by-laws before the council. Then the council had given its concurrence. It seemed to him that if the fact of the council having declined to adopt a by-law were to prevent the society from adopting it then inaction on the part of the council might indefinitely prevent action on the part of the society.

The by-laws stated that any change in them required the concurrent action of both society and council. There was no reason why it was necessary that the council should act first.

The last speaker had made a point of the question of courtesy. It seemed to him that the rule of courtesy should work both ways and that the society should be treated with as much courtesy as any one else. Those who had signed the notice had selected the hour they did because there was no other during the day, and because any amendment to the by-laws must be acted upon at an adjourned meeting. He believed this to be a legal meeting of the society. It seemed to him very important that the society should know its position. It had responsibilities and duties as well as pleasures. One of these duties was to attend to its business. He thought that when the society adjourned it should be for the purpose of discussing the question postponed from the last year.

DR. WILLIAMS said that by general consent it had been admitted that there was no necessity for a meeting because the matter lay on the table of the council. Till the publication of the notice in the Medical Journal only two gentlemen had expressed themselves as desirous of holding a meeting. The general consent was that there was no necessity, and therefore the meeting had been dispensed with.

DR. G. C. SHATTUCK said there was no reason why a meeting should be held. That was not a natural reading of the records. The society had adjourned in view of some action of the council; that action not having been taken, the thing fell through. Were it not so, this was not the time nor place. It would be impossible to discuss the matter fairly. If it had rested during a hundred years, why should it have been brought up at a time when it could be neither fairly nor freely discussed? He would not have it put on anything but its merits. He was ready to go into the question fully.

DR. H. J. BOWDITCH rose to a point of order. The question was not of the admission of women, but of adjournment.

DR. SHATTUCK. "It is a question" —

DR. BOWDITCH called Dr. Shattuck to order.

DR. WILLIAMS thought Dr. Shattuck was right.

DR. BOWDITCH. "The question is whether the society shall have a meeting or not."

DR. SHATTUCK said it seemed to him a question whether there should be a meeting at eight for a purpose. He was discussing whether that purpose could be accomplished. He took the ground that there then would not be time for a full discussion.

DR. C. P. PUTNAM made a correction with regard to the preamble to Dr. Bronson's motion. It was not a preamble but merely Dr. Bronson's reason for his own vote.

DR. WILLIAMS said that the society voted to meet for that purpose, and for no other.

DR. C. P. PUTNAM said the preamble gave the reason for making the motion, but not members' reasons for adopting it.

DR. PUTNAM asked permission to read the following legal opinion.

DR. S. CABOT, AND OTHERS:

Gentlemen, — Our opinion is asked as to the effect of the vote of the Massachusetts Medical Society at its last annual meeting, that when this meeting adjourns it does so to meet at the place of annual meeting, on Tuesday preceding the annual meeting of 1881, at four P. M.

We have no doubt that the meeting stands adjourned in accordance with the terms of the vote, and, the annual meeting for this year having been fixed for Wednesday, June 8th, that the adjourned meeting should be held on Tuesday, June 7th, at four P. M. The fact that the mover of the vote stated that he made the motion in view of a contingency which has not arisen has no bearing whatever on the effect of the vote when passed. Other members may have voted for his motion from wholly different motives, and their motives and his are alike immaterial. If the officers of the society are not present, a *pro tempore* president and secretary should be appointed, in accordance with By-laws XXIII. and XXVI. Very respectfully yours,

RUSSELL & PUTNAM.

DR. WILLIAMS said that the contingency was stated and that the society voted to meet if that contingency arose. Perhaps the society would have voted in some other way, had any other motive been presented.

DR. CHADWICK did not see what the motive had to do with the question. His own motive might have been very different from that of others. The vote was all the society adopted. Nothing else was binding. He therefore could see no reason and no legal right why the society should be told that it cannot discuss the question. With regard to time of the meeting, if there was any discourtesy it was not on the part of the men who called it, for it was the only time available for the passage of an amendment to the by-laws. To show that there was no discourtesy on the part of the friends of the meeting, he would say that he had gone to the president and asked him if there could be no other time appointed. He had declined to consider the question. There was no discourtesy whatever; if any, it was in disregarding the desire of the society expressed at the last meeting.

DR. HILDRETH did not understand the condition of this question in the council.

DR. WILLIAMS said it lay upon the table of the council. Usage requires that the council should act first and that the larger body confirm. The society would have met if the council had taken any action. Therefore there is nothing for the society to act upon.

DR. HILDRETH said he understood the chair to say that, as the matter was on the table of the council, that precluded any action of the society, now or at an adjourned meeting at eight.

DR. CHADWICK said he would like the president to point out any by-law that gives precedence to the council over the larger body. There was such a provision in the old by-laws. The present left out that clause. Therefore the change was made for the very purpose that the society might have the right to act first. That the society has the power to do this was shown on two occasions, when action having been taken in the society, the matter was referred to the council for concurrence.

DR. WILLIAMS read from the records the report of the proceedings on the two occasions referred to, and showed that the first had been wrongly quoted. On the second it was shown by a late part of the record that the society had been in much confusion. He asked if the society was willing to be guided by such precedents.

DR. CHADWICK then asked if on the second occasion the by-law had not been adopted by the council, and become thereby a by-law of the society.

DR. WILLIAMS replied that it had been, after much discussion.

DR. CHADWICK asked if it had not thereby become a by-law of the society.

DR. WILLIAMS replied that it had.

DR. WILLIAMS then read By-law XL. of the edition of 1850, to the effect that any amendment of the by-laws must originate in the council.

DR. C. P. PUTNAM asked why that by-law was not in the present edition.

DR. WILLIAMS said it was not in the present by-laws, but it had never been repealed. The matter had been regulated by usage.

DR. HILDRETH asked whether the present by-laws were defective.

DR. WILLIAMS said the vote which established the present by-laws repealed all previous ones which were inconsistent or superfluous. The present edition did not contain them all.

DR. HILDRETH said that either the edition of 1850 was correct, or the later one is not. If the by-laws of 1850 were good this meeting was useless. The question seemed to him to be whether our present by-laws are correct or not.

DR. J. J. PUTNAM said that men had come with one preëminent interest in view. It had been stated by certain members that they went to the president, and were told by him that no such meeting as this could legally be held. Many feared that such a meeting as this would have unpleasant consequences. It would not have been done had it not been felt that this was a serious matter, — more serious than the question of the admission of women. The trouble was that many felt that the centennial anniversary of this society should not be marked by such a precedent as this. The ruling of the officers that measures can only originate in the council he did not believe to be just. They had looked up the subject, and thought that their position was correct.

This was the opinion with many who did not especially favor the admission of women, and who nevertheless wished to have this meeting. It seemed to him important to know just where the matter stood, and to determine whether it was in any one's power to declare that an adjourned meeting cannot be held because the meeting was supposed to be called for a certain purpose.

DR. HILDRETH said that in order to find out whether or not the society has a right to originate a by-law he moved that the chair appoint a committee of three, to report at some subsequent meeting of the society, to consider the question whether the society has the power to originate a statute *de novo*.

DR. CUTLER, of Charlestown, said that the by-laws of 1850 contradicted the by-laws of 1874; they were inconsistent.

DR. WILLIAMS said he took the view of Dr. Putnam. The chair never said that the meeting could not be held. He merely said, that by general consent the meeting had been dropped. He knew of no other business. Two gentlemen did not seem to him enough. Had a quorum desired it he would have arranged for the meeting. He had no desire to suppress it. It might have been held with no member present. This was all he felt accountable for. There was no inconsistency in the by-laws. It was absurd to say that the council should be able to nullify the acts of the whole society.

DR. J. J. PUTNAM. The council was for the convenience of the larger body merely, and whenever the latter wished to take action it could freely do so. On the question of the admission of women it was peculiarly adapted to the discussion of the larger body.

DR. CHADWICK moved, as an amendment to Dr. Hildreth's motion, that the council be requested to appoint a committee of three to act with the committee appointed by the chair, and take legal advice. Dr. C. P. Putnam withdrew his motion.

DR. S. CABOT said this was a regular meeting of the society, and it should have been the duty of the president and secretary to call a meeting.

DR. WILLIAMS. It is an adjourned meeting, and adjourned meetings do not require to be notified.

DR. WILCOFF of Cambridge moved a further amendment, that the committee report at the October meeting of the council.

DR. CHADWICK moved an amendment to the effect that the committee report whether it is necessary to reprint by-laws. Motion put and carried.

DR. A. T. CABOT said: When this adjourned meeting was ordered at the last annual meeting many who favored the admission of women to the society looked forward to it as the first opportunity the society had had for the full discussion of this question. A full meeting at this time had been made impossible by the arrangement of the harbor excursion for this hour. When it was seen that this would be the case, the plan was formed of adjournment to the evening, that as full an attendance as possible might be had, it being felt that so important a question should be acted upon by the full society. It seemed now unlikely that even this evening's meeting could be a full one, as a number of attractions were offered to the Fellows for the same hour. This meeting had accomplished one of the objects for the sake of which it had been insisted upon, and which had been mentioned by Dr. J. J. Putnam, namely, that it had prevented the establishment of the precedent that the Fellow can be prevented from hold-

ing an adjourned meeting at the time determined on by them. This question, considered in its legal aspect, was perhaps more important than that other object for which this meeting was desired.

As it was wished that there should be a full meeting for the discussion of so important a question as the admission of women, and as it seemed unlikely that there would be a full attendance this evening, he would ask Dr. C. P. Putnam, who offered the motion to adjourn to eight o'clock, and who felt, he knew, as he himself did, to move an adjournment *sine die*.

DR. C. P. PUTNAM said he agreed with Dr. Cabot in saying that they did not wish to spring the subject upon the society. It must not be forgotten that the secretary had answered in writing a note inquiring about the meeting, and said he knew of no such meeting. The president had answered a similar note that he had called no meeting except those of the printed programme. Dr. Putnam said this was undoubtedly true, but it was equivalent to saying that there was to be no adjourned meeting. Dr. Williams said that the question had been whether he had called a meeting, and he had answered that he had called no meeting. Dr. Putnam then moved to adjourn *sine die*. Carried.

MEETING OF THE COUNCIL OF THE MASSACHUSETTS MEDICAL SOCIETY.

The usual meeting of the Council was held at the Medical Library, Boylston Place, on Tuesday evening, June 7th, at seven o'clock, the president of the society, Dr. Williams, presiding.

The secretary read the names of new and deceased members.

The annual report of the treasurer was presented; the auditing committee reported the accounts to be properly vouched and correctly cast and the report was accepted. The receipts for the current year have been \$8160.74; the expenditures \$6617.50; the balance, \$1543.24, remains in the treasury. The funded property of the society has remained without change, the amount being \$31,420.17.

The committee on finances recommended that ninety per cent. of the balance in the treasury, being \$1388.92, be distributed among the several district societies.

The committee on membership reported the several lists of names of members to be retired, allowed to resign, and to be dropped from the roll.

The following were elected to honorary membership: William Bowman, F. R. S., London; Professor Franz Cornelius Donders, Utrecht; Professor George Rolleston, M. D., Oxford; Sampson Gamgee, F. R. S. E., Birmingham.

DR. GEORGE C. SHATTUCK, for the committee on publication, reported that no essay was presented in competition for the society's prize.

DR. LANGMAD, of the committee on the library, reported that proper examination of the library of the society was made and the books found in good condition and properly cared for; he also read, in the absence of the librarian, the report, which gave a list of the additions made during the year.

The special committee which was appointed to appear before the legislature to attempt to obtain proper legislation on the commitment of lunatics to asylums, reported through the chairman, Dr. CUSHING, that the act proposed they were unable to carry through, but a modified form of the act proposed was passed, which was far from satisfactory, and it was to be hoped that

farther legislation would be obtained. It was voted by the Council that the committee be continued and empowered to take such action as they may see fit.

The committee appointed, on petition of the censors of the Suffolk District, to obtain greater uniformity in the examination of candidates for membership, reported, through their chairman, Dr. Hosmer, that the by-laws of the Massachusetts Medical Society fix with precision the conditions under which any board of censors may grant or refuse such application. Said by-laws enumerated at length the qualifications necessary for membership. The committee suggested that in addition to the questions now contained in the certificate of qualification of candidates the following should be added: Have you ever been examined by any board of censors of the Massachusetts Medical Society? If so when and where? It was suggested that names and residence of men rejected by one board should be reported to all the other boards, and that the secretary of the censors of the Suffolk District invite all the censors of the different districts to meet, either by full board or by delegates, to arrange for a conference of censors of the different districts at stated intervals to discuss questions in which they have common official interests. A suggestion was also made for the appointment of a standing committee of the Council on medical diplomas, whose duty it shall be to propose and submit a list of those American medical colleges which deserve to be recognized for purposes set forth in By-Law I. of the society.

The report was accepted and committee appointed to carry out the last suggestion. Drs. C. W. Swan, J. Spaulding, and J. Crowell were appointed.

The joint committee, in accordance with the request of the society at the afternoon meeting, was announced. On the part of the society, Drs. J. L. Hildreth, W. Cogswell, and Alfred Hosmer; on the part of the council, Drs. H. I. Bowditch, S. D. Presbrey and S. E. Stone.

The treasurer reported that he had received from Dr. Cotting the offer of an additional one thousand dollars to be added to the Cotting Fund, the income of which was to be devoted to the provision of lunches at the councilors' meetings, and also the gift from Dr. Cotting of a silver pitcher presented to him by the late Dr. George Heywood for faithfulness as a student under Dr. Heywood.

In accordance with report of committee on nominations the following were elected officers for the ensuing year:—

Dr. Henry W. Williams, Boston, president; Dr. T. H. Gage, Worcester, vice-president; Dr. Frank W. Draper, Boston, treasurer; Dr. Charles W. Swan, Boston, corresponding secretary; Dr. Francis W. Goss, Roxbury, recording secretary; Dr. David H. Hayden, Boston, librarian; Dr. Pliny Earle, Northampton, orator; Dr. George S. Osborne, Peabody, anniversary chairman.

The following standing committees, nominated by the president, were appointed by the council:—

Of Arrangements: Drs. F. C. Shattuck, E. G. Cutler, E. H. Bradford, C. E. Wing, A. T. Cabot, H. C. Haven.

On Publication: Drs. G. C. Shattuck, R. M. Hodges, B. E. Cotting.

On Resignations: Drs. J. Ayer, F. Minot, D. W. Cheever.

On Finances: Drs. C. D. Homans, W. W. Wellington, B. S. Shaw.

To Procure Scientific Papers: Drs. C. W. Swan,

F. W. Paddock, G. S. Stebbins, J. R. Chadwick, R. H. Fitz.

On Ethics and Discipline: Drs. R. L. Hodgdon, G. J. Townsend, G. E. Francis, A. H. Johnson, C. Howe.

The time and place of next meeting were fixed for Boston, the second Wednesday in June. Adjourned.

In the evening, by the courtesy of the trustees, the Museum of Fine Arts was open to members of the society and their lady friends. The rooms were brilliantly lighted, and were visited by a large number of the members. General Loring received the guests, but the visit was entirely informal, the visitors coming and going from time to time at their own pleasure.

At half-past eight a reception was tendered to the society by Dr. H. W. Williams, the president. His house, No. 15 Arlington Street, was brilliantly decorated with flowers, and was crowded. The doctor's hospitality was accepted by a very large number of physicians. Among those present were: Mr. Harrison, of Liverpool, England; Dr. McCuen, of Chester, England; Dr. Giddings, from South Carolina; Dr. Jacobi, of New York; Dr. Fordyce Baker, of New York; Dr. Pillsbury, of Newark; Dr. Goodnow, of Quebec; Dr. Cann, President of the New Hampshire Society; Dr. Caswell, President of the Rhode Island Society; Dr. Horr, of the United States Navy; and Dr. Lawrence Turbull, of Philadelphia. There was no speech-making, and the evening was devoted to conversation and the interchange of professional reminiscences.

WEDNESDAY (second day). In the forenoon there were the usual surgical visits at the Massachusetts General Hospital and the City Hospital; the Carney Hospital and the Children's Hospital were also open to visitors. By courtesy of the officers in charge there were also open to the doctors the Museum of Fine Arts, the Institute of Technology, the museum of the Natural History Society, the Warren Museum at the medical college on North Grove Street, and the Warren Museum of Natural History on Chestnut Street.

The usual trade exhibits of drugs and surgical appliances, which have of late years become a feature of medical society meetings, were this year replaced by an exhibition of a more elevated character. In the lower Horticultural Hall was a comparative and historical collection of medical books, surgical instruments, and curious and useful objects belonging to the past and present times. On one side were the drugs in use more than one hundred years ago, and which still retain their ground; drugs introduced within the past century,—a large collection; discarded remedies, drugs, and chemicals; new remedies, not officinal, about fifty. A very extensive and complete collection of surgical instruments and appliances occupied the centre of the hall. Nearly two hundred botanical specimens from the botanical gardens, Cambridge, adorned the walls, and a most interesting feature of the exhibition was the botanical models, made in Paris, for the college or pharmacy. A rare department of the display was the large and brilliant collection of illustrated medical works. This collection was a most noticeable feature of the meeting. It was continued during a part of Thursday, and the large attendance on that day showed the appreciation in which it was held. We dismiss it for the present with brief mention, hoping to be able to refer to it again at greater length in some future number.

At eleven o'clock the society was called to order for

the one hundredth annual meeting. The record and names of new and deceased members were read; eighty-two members have been admitted and thirty members have died during the year.

The record of the trial of Dr. C. S. May was read, and in accordance with the recommendation of the board of trial he was expelled by the society.

The treasurer's report was then read.

Dr. JEFFRIES then read the following preamble and vote, and moved its adoption:—

"Whereas, A petition has been presented to Congress, asking for the calling of an international commission to consider and agree upon standard methods of testing visual acuteness and color-blindness, and standard requirements of the necessary qualifications in the navies and merchant marines,

"*Resolved*, That the Massachusetts Medical Society heartily approve of this proposed international committee, and hereby direct the secretary of the society to transmit this vote to Congress when next assembled."

The vote, which was passed, is similar in effect to votes and resolutions adopted at the sixteenth annual meeting of the American Ophthalmological Society, and at the forty-eighth annual meeting of the British Medical Association, the resolutions adopted by the last-named society being indorsed by the sixth international congress of ophthalmology which met at Milan in September last.

THE PRESIDENT then introduced the following named delegates from other State societies: Dr. J. L. Boline, of Newton, N. J.; Dr. M. V. B. Dunham, of Greenfield Hill, Conn.; Dr. W. R. White, of Providence, R. I.; Dr. S. G. Wolcott, of Utica, N. Y.; Dr. J. D. Littlefield, of Titusville, Pa.; Dr. Lawrence Turnbull, of Philadelphia; Dr. T. J. W. Pray, of Dover, N. H.; Dr. S. Lawton, of Maine; and Dr. Cleveland, of Connecticut.

The president welcomed the delegates, and invited guests, and Dr. TURNBULL read a short address in which he gave the dates of various events in the early medical history of Pennsylvania. The first course of anatomical lectures in Philadelphia was delivered in 1762. The first medical school was established in 1765, with Benjamin Franklin president of its first board of trustees. Dr. Turnbull referred gracefully to the efforts of the daily press in Philadelphia, which had been successful in the destruction of the diploma mills of the city.

Dr. GROSS was especially introduced to the society.

Dr. HOBBS, of Arlington, moved that when the society adjourn it do so to meet on the Tuesday preceding the next annual meeting, at four o'clock P. M., the secretary to notify members of such meeting. The object of such meeting, it was explained, was the discussion of the amendment of certain by laws.

On motion of Dr. ENDS it was voted that the committee of arrangements be instructed to continue the exhibition in the lower hall during Thursday in order that it may be examined by all of the members of the society who desire to see it. The thanks of the society were tendered to the committee who had prepared this exhibition. Thanks were also tendered to the physicians of Boston and vicinity for the courtesies they have shown the visiting members of the society.

At twelve o'clock the doors were closed, and the society adjourned to the annual discourse by J. COLLINS WALKER, M. D., of Boston, a portion of which is published in the present number of the JOURNAL.

At the close of the orators' thanks of the society

were voted to the two orations of the centennial meeting and to the various bodies and gentlemen that have extended courtesies to the society. The members then adjourned to the neighboring Music Hall to partake of the annual dinner. The exercises at the dinner will be reported in the JOURNAL of next week.

Recent Literature.

A Practical Treatise on Fractures and Dislocations, By FRANK HASTINGS HAMILTON, A. M., M. D., LL. D., etc. Sixth American edition, revised and improved. Illustrated with three hundred and fifty-two wood-cuts. Philadelphia: Henry C. Lea's Son & Co. 1880.

This able work, which is fairly encyclopædic in character, is once more offered to the profession after thorough revision by the author. The section devoted to Fracture of the Patella has been entirely rewritten, and incorporates a study of one hundred and twenty-seven cases, which have been published in a single volume, and were reviewed in the JOURNAL some months since.

A new chapter on General Prognosis is added, and includes a consideration of the views held by Dr. L. A. Sayre on the treatment of fractures, as presented by him in 1874.

Dr. Hamilton has reviewed that series of cases with impartiality, but does not coincide with the author in his conclusions, on the ground that his evidence is incomplete. The point in question is the amount of shortening to be expected after fractures of long bones. It is safe to assume that the views held by the profession accord with those of Dr. Hamilton, and that it remains for Dr. Sayre to offer additional and competent proof in support of his theory. Dr. Hamilton states that "There is no danger, perhaps, that such extraordinary statements will affect the opinions of experienced surgeons in any part of the world, but they will be read, probably, by many inexperienced surgeons, and may with them have the weight of authority; and, indeed, they have already been quoted by the author of a treatise on Civil Malpractice, intended as a guide to jurists, and which is widely read by lawyers and medical men. The author has, however, modified the force of the authority by expressing his belief that, while such results might be possible with Dr. Sayre, they can hardly be expected from the "ordinary" surgeon; but how will it be with Dr. Sayre's peers, nearly all of whom, in every part of the world, and with the same appliances used by him, declare their inability to make all long bones unite without shortening, and who, indeed, affirm that with them union without some shortening is the exception and not the rule, a doctrine against which Dr. Sayre entered his earnest protest both at Detroit and Buffalo.

"Our personal interests, as well as the interests of science and humanity, demand that we shall know positively whether shortening can always be avoided, or even made the exception rather than the rule, but we need something more than mere assertion, however notorious may be the author's reputation for acuracy of observation and for truthfulness of statement."

The publishers deserve great credit for their enterprise in presenting this and others of their standard works in such attractive shape. The paper and printing are excellent, and the binding superb.

Medical and Surgical Journal.

THURSDAY, JUNE 16, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE CELEBRATION OF THE CENTENNIAL ANNIVERSARY OF THE MASSACHUSETTS MEDICAL SOCIETY.

THE announcements given to our readers from time to time for the last few weeks of the various steps proposed for the celebration of the one hundredth birthday of the Massachusetts Medical Society, gave promise of an unusually full and interesting occasion, and we knew we risked nothing in advising members to avail themselves of opportunities presented to them. The particularly successful realization of the plans proposed has unquestionably exceeded the most sanguine expectations.

Considering the state of moral turpitude to which the present month of June has reduced it, the weather was fairly favorable; we do not doubt, though, that the continued east wind is responsible for the incipient fog which threatened to envelop the society one afternoon, but which was dissipated by an irresistible centennial good humor.

The officers of the society, and especially the committee of arrangements, are to be heartily congratulated upon the results which they accomplished. The absolute punctuality and precision with which so large a body of men, from six to eight hundred, was transported from one point to another, from Boston to Brighton, from thence to Cambridge, and from a luncheon at Memorial Hall to the steamer at the wharf for an excursion down the harbor, each point being reached exactly on time except the final return to the wharf at Boston, which was delayed five minutes by an envious tide, could only have been achieved by a rare executive management, which makes it evident that the medical profession has absorbed a talent destined for the supervision of a granger trunk line.

The exhibition of instruments, books, drugs, etc., was not only a grateful successor to the jumble of advertiser's wares familiar to similar annual meetings, but proved so instructive and interesting that it was voted to keep it open an additional day. The JOURNAL will contain a careful account of this display. The different receptions were well attended, and much enjoyed.

About seven hundred and fifty members availed themselves of the excursion around the harbor, and eight hundred and seventy-three partook of the annual dinner, which was succeeded by the toasts and speeches.

in connection with which the word *usual* would be inappropriate.

It is not often that an audience so large and so intelligently appreciative is brought together, and it certainly is even more rare that any audience is fortunate enough to listen to such uniformly excellent speaking, to which was added a very brilliant and sympathetic poem by Dr. O. W. Holmes, read in his own admirable manner.

The only duty remaining to the JOURNAL to perform in connection with an anniversary upon which it has felt compelled to lavish so much praise, is to give its readers a full and accurate report of all that was said and done and seen, and such provisions were taken as will enable it to discharge this duty with satisfaction to its readers.

MEDICAL NOTES.

—If the proverbial success of a third trial does not fail them, we permit ourselves to hope that our columns will on this occasion do complete justice to the Latin inscription on Dr. J. B. S. Jackson's portrait.

JOHANNIS B. S. JACKSON, M. D.

Anatomiei Pathologiei Præstantis: Anatomie Pathologicæ Prof. Harv.:

Musei Pathologicæ conditoris:

Societatis pro Medicinæ Progressu constitutæ decoris et præsidii:

Hanc tabulam Sodales ejus grati in Memoriam dedicant.

A. D. MDCCCXXI.

—Two cases of small-pox appeared in Boston the week ending Saturday, June 11th, and seven cases in Fall River during the same period.

—Last April Dr. Doremus, the younger, obtained some milk from the female elephant who gave birth to a calf at Philadelphia last spring. This milk has been analyzed by Professor Doremus; it approached the composition of cream, but it did not have its consistency. It was pleasant in flavor and odor, and very superior in these respects to goat's milk, and fully equal to cow's milk. The elephant calf weighed two hundred and thirteen and one half pounds when born, March 10, 1880, and gained seven hundred pounds on this milk diet in a year.

—The *Philadelphia North American* is evidently not inclined to shut its eyes to coming evils. It says: "Doubtless a good many people failed to get vaccinated last winter because they thought the small-pox epidemic would disappear this summer. So far as this city is concerned, it is evidently going to remain with us far into the next year, but there is no occasion for alarm if the important duty of vaccination is attended to."

—The Chicago Medical Society has elected Drs. S. J. Jones and R. N. Isham as delegates to the international convention at London.

—According to the daily papers there is an "artist" physician in New York who makes a specialty of extracting the red bloom from topers' noses and making them of a virgin whiteness. Patrons are said to be plenty.

—Several of those unfortunate eases having re-

cently been reported in which persons suffering from illness have been treated for drunkenness, a correspondent of an English contemporary, makes the following suggestion, which, at any rate, has the merit of common sense. It is, that all members of the police force should be instructed to treat every case of insensibility as if it were of the gravest nature, and always to remove the patient as quickly as possible to the nearest hospital or medical man's house. It is urged that if this rule was strictly enforced among the police, it would do far more good than any amount of lectures concerning that most difficult question — differential diagnosis of cases of insensibility from drunkenness, apoplexy, poisoning, etc.; and in the end, if the case really resolved itself into one of drunkenness only, the delinquent might then be brought before the magistrate to be dealt with according to his deserts.

NEW YORK.

—The deaths from infectious diseases during the first five months of 1881 and 1880, respectively, were as follows:—

	1881.	1880.
Measles	167	404
Scarlet fever	884	176
Small-pox	212	2
Diphtheria	895	371
Croup	507	334
Typhus fever	91	334
Typhoid fever	139	72
Whooping-cough	82	124

—The eight free public baths belonging to the city were opened for the season on June 1st; Mondays, Wednesdays, and Fridays being reserved for females, and the other days of the week for males.

—Some time since Governor Cornell issued a proclamation requiring the proprietors of the oil refineries and various factories giving rise to injurious and offensive emanations on the Long Island side of the East River to abate the nuisances complained of in connection with them, and granting them till the 1st of June in which to accomplish this. Most of the establishments claim to have now applied efficient devices for suppressing the bad odors, but the people who live in the neighborhood state that they are unable to detect any appreciable improvement.

CHICAGO.

—The present appearances indicate for this summer an unusual measure of sickness. In the death reports cerebro-spinal meningitis and typhoid fever occur with unusual and very suggestive frequency. Latterly typhoid fever has caused about fourteen deaths each week, while cerebro-spinal meningitis has caused half as many more. Typhoid and remittent fevers are prevailing also in villages near Chicago. Small-pox still commands public attention, notwithstanding the warm weather. The small-pox hospital is full of patients and for this reason selected cases are allowed to remain at their homes. Two days of the past week witnessed the report at the health department of eleven cases of death from this disease.

—The rocky condition of our drinking water which existed during a few days following the spring flood of the Chicago River has given place to that of

the crystal clearness and purity of the Lake Michigan water in its unpolluted state. It is now a positive luxury to drink it. Now, also, we can calculate more nearly how much of the diarrhoeal disorders which existed in our midst during those days of swollen river was due to the bad water. As the turbid condition was due to admixture with our drinking water of the muddy water of the river, carrying with it some quantity of sewage, the drinking water could not be otherwise than unwholesome, and some of the many cases of diarrhoea were doubtless due to this fact, while many cases that otherwise might have occurred were doubtless aggravated by it. But the epidemic referred to cannot be charged in a wholesale manner to this cause, for a similar epidemic existed at the same time in most of the suburban towns about Chicago and in many villages of the Northwest at a distance. This shows that some cause residing with the atmosphere or the earth was mainly responsible for the epidemic here.

—The Illinois legislature, just adjourned, enacted several laws of interest to the profession. One was an act for the regulation of the practice of dentistry, another governs the practice of pharmacy. Hereafter no person may practice dentistry in Illinois unless he is a graduate of a dental college, or of a medical college, or has practiced dentistry ten years outside the State, or is a practicing dentist here at the date of the passage of the act, or unless, failing in all these qualifications he passes an examination before a board of examiners, appointed by the governor, and consisting of five practicing dentists. It will be seen, therefore, that, so far as the resident dentists, whom the law finds engaged in actual practice, are concerned, it does not disturb them, farther than to require them to take out a license from the board of examiners within six months after the passage of the act. Failing in this they are required to pass an examination before the board, the same as in the case of a beginner in the profession. Physicians must take out a license if they desire to pursue dentistry farther than the pulling of teeth. Violation of the law incurs a fine of twenty-five to fifty dollars for each offense, the fine to be paid into the common-school fund. Licenses must be registered with the clerk of the county in which persons practice within six months of the issuance thereof, or a forfeiture of the license results.

The pharmacy law is less plain and simple in its provisions. The law provides for the registration of all pharmacists, creates a board of pharmacy of five practical pharmacists to be appointed by the governor, whose duty it is to register the pharmacists of the State, to examine certain classes of them, and grant licenses to practice, etc. Pharmacists who were engaged in actual practice at the time of the approval of the law are registered on the proof of that fact. Drug clerks not less than eighteen years old who have had two years' actual experience in compounding prescription may be registered, on presentation of these facts, as "registered assistant," but this does not allow a man to engage in the business on his own account; for that purpose at least five years of practice is required. Graduates of medicine, graduates of reputable schools of pharmacy, and licentiates of the boards of pharmacy

are to be licensed and registered on these facts being shown to the board. All other persons are to pass an examination in pharmacy before the board in order to gain a license. The penalty for the violation of either of these laws is a fine for each offense.

The pharmacy law makes it an offense punishable with a fine of seventy-five to one hundred and fifty dollars for each offense to adulterate in any way drugs and medicines; it also makes it an offense to sell certain medicines known as poisons without attaching a label "poison," or to sell them to a person under fifteen years of age.

Both these new laws, it will be seen, are copied to a large extent from the law regulating the practice of medicine, which has been in force several years with good effect.

—Dr. H. M. Bannister, the junior editor of the *Journal of Nervous and Mental Diseases*, has been appointed an assistant to Dr. R. S. Dewey, superintendent of the Insane Hospital at Kankakee, Illinois, near Chicago. This hospital has just commenced to receive female patients, the new wing of the structure for that purpose having just been completed. Probably there is not a better managed hospital for the insane in the West than this one, and the addition to the medical corps of the institution of a man of the erudition, in the specialty of mental diseases, of Dr. Bannister is one at which all concerned should be congratulated.

Miscellany.

LETTER FROM ST. LOUIS.

Your reporter had the pleasure of attending the meeting of the Missouri State Medical Society held at Mexico, Mo., May 17th, 18th, and 19th. Mexico is a thriving "city" of some six thousand inhabitants (there is no other form of municipal organization in many of the Western States than that of the city), situated in the midst of a very fertile prairie country, which is rapidly filling up with an excellent population. The physicians and other citizens of Mexico are very enthusiastic as to the prospects for their city.

The attendance at the Association was said to be larger than has ever been known except when the sessions were held in St. Louis and Kansas City. The people of Mexico threw open their doors, and entertained most hospitably all who would accept the hospitality, while there was ample accommodation at the several hotels for those who preferred to entertain themselves.

The papers read before the Association were prepared with care, and the discussions in many cases were spirited and interesting. Among those of special value and merit were Dr. Lutz's paper on Gastrotomy, being the report of a case in which he had operated successfully for stricture of the œsophagus due to cancerous growth. The patient has lived comfortably for seven months since the operation was performed, and Dr. Lutz expressed a confident hope that, as the present indications are so favorable, his

patient will live longer than have any of those who have undergone the operation before. In the discussion which followed this case Dr. A. J. Steele, of St. Louis, gave some interesting details of the case of his own child, who is the subject of a cicatricial stricture of the œsophagus, due to having accidentally swallowed some lye. In treatment he has avoided the use of sounds or bougies except for the purpose sometimes of pushing on portions of food that had lodged at the site of the stricture. While for some years the child was dependent upon milk almost exclusively for nourishment, she has now improved so that she can eat much of the food which children ordinarily enjoy.

Dr. Willis P. King, of Sedalia, read a paper upon the Cooling Bath in Fever. He takes the ground that elevation of temperature is the chief danger to be averted in a large part of "the ills that flesh is heir to," and especially the flesh of children. He asserts that in all cases where there are convulsions, present or imminent, elevated temperature is found, and that the reduction of that temperature by means of cool water is the quickest, surest, safest, and readiest means of averting the danger of cerebral or spinal complications. He condemns the common practice of putting into water of high temperature, as high as that of the body itself, a child in convulsions, as being unphilosophical as well as useless, and claims the happiest results from the use of cool baths, say of a temperature of 90° F. lowered by the addition of cold water to 80° F. or 70° F. He uses this treatment, in conjunction with whatever medication may be indicated, in all diseases where the elevation of the temperature is such as to produce marked nervous disturbance.

Dr. J. M. Allen, of Liberty, the retiring president, detailed the results of the attempt made during the last session of the legislature to secure efficient action with reference to the establishment of a state board of health, and also with reference to the regulation of the practice of medicine. Though the attempt failed this time, he urged renewed efforts in this direction, and is sanguine of ultimate success. He urged the importance of requiring higher qualifications in those applying for admission to the ranks of the profession. He is deeply interested in the organization of county and district medical societies through the State, and spoke strong words as to the importance of such organized work to promote the best interests of the profession.

Dr. C. A. Todd, of St. Louis, reported a case of Asthma Dependent upon Nasal Polypi, and which was cured by removing the polyps. In the discussion that followed this paper an interesting case was related by Dr. A. W. McAlister, of Columbia, in which an attack of asthma could be excited at will by simply touching the external orifice of a urethral fistula.

Illusions, Hallucinations, and Delusions was the title of a paper by Dr. C. H. Hughes, of St. Louis, who, as a medical expert in cases where there is a question as to the sanity of an individual, has had occasion often to define these phenomena of abnormal mental action. He gave clear and lucid definitions

and illustrated the subject with practical cases of interest.

Dr. G. Hunt's paper on Hygiene was considered such a valuable contribution that the corresponding secretary was instructed to arrange for its publication in one of the daily papers, in order to secure its circulation as largely as possible among the laity, under the sanction of the Association.

Dr. B. F. Wilson, of Salisbury, read a paper on Diphtheria, which elicited a good deal of discussion.

The Relation of the Specialist to the General Practitioner, was the subject of a paper by Dr. Wm. Dickinson, of St. Louis.

The officers of the Association for the coming year are Dr. W. P. King, of Sedalia, president; Drs. B. J. Milam, A. E. Gore, G. Hunt, E. A. Waggoner, B. F. Wilson, vice-presidents; Drs. C. A. Todd and J. H. Duncan, secretaries; Dr. Wm. Dickinson, corresponding secretary; and Dr. C. A. Thompson, treasurer.

On Thursday evening a banquet was given to the Association and ladies by the physicians and citizens of Mexico. It was a most enjoyable occasion, and is spoken of by the local press as being one of the most brilliant and elegant entertainments ever held in that place. An interesting feature of the banquet was the absence of any stimulating beverages, and surely no one who attended this banquet will say that they are necessary to a thoroughly enjoyable occasion.

The next meeting of the Association will be held in Hannibal on the third Tuesday of May, 1882.

LETTER FROM NEW YORK.

SANITARY MATTERS IN NEW YORK.

MR. EDITOR, — The sanitary outlook in New York, it must be confessed, is not as encouraging as might be wished; and one of the most unpleasant features in connection with the present condition of the city is undoubtedly the utter indifference to the health of its inhabitants, as well as the entire lack of appreciation of the essential requirements of such a community, which has of late been shown by the majority of the members of the state legislature, by whom, under the existing system, the affairs of the metropolis are arbitrarily governed. As was recently remarked by the *Journal of Commerce*, no city in Europe is as badly governed as New York. No emperor or king dares to abuse a great city in his dominions as the Albany legislature abuses it, and if any European city were as shabbily treated by the governing power its citizens would rise in rebellion. The European ruler may be a tyrant, the article continues, but he is a benevolent one, while the Albany tyrants are malevolent in all they do to New York; and that city is much happier which is governed by a resident tyrant than by one living a hundred and fifty miles away, who never goes to see it except on a debauch.

The special matter in which the state legislators have recently been so derelict is, of course, that of the cleaning of the New York streets, about which there has been so much agitation; and the simple reason why this important object has been so shamefully neglected has been the fear of the loss of political patronage and spoils. As is well known, the garbage and filth have

not been properly and thoroughly removed from the streets for a number of years, and at last the demand for reform in this respect became so urgent that a bill securing the full accomplishment of the desired end was drawn up and presented to the legislature by a committee especially appointed for the purpose at an immense meeting of the very best citizens; the bill receiving in addition the full sanction and indorsement of the mayor, who pledged himself in the most solemn manner to carry out its provisions in such a way as to withdraw the entire matter from the field of party politics. As the rate of mortality had been increasing to such an extent that there were 2306 more deaths in the city during the first quarter of this year than in the first quarter of 1880 (representing about 65,000 more cases of sickness), and as it was the unanimous testimony of all the ablest New York physicians that this result was undoubtedly due, to a large extent, to the filthy condition of the streets, it might have been supposed that the subject would so appeal to the common sentiment of humanity, at least in the members of the legislature, that the bill would be passed at once and without a dissenting voice. But instead of this, it was promptly defeated, and for nearly three months the Assembly was engaged in devising some street-cleaning law by which the streets would still be left dirty and the enormous sums of money appropriated for the express purpose of cleaning them still flow into the hands of the partisan leaders or be dispensed for partisan purposes. As was forcibly remarked by one writer recently, "If Nero fiddled when Rome was burning, the spectacle is fairly matched by the heartless scheming of our representatives while the people of New York are dying. We say 'our representatives' from habit, for the existing situation does not justify the phrase. The people no longer have representatives: one ward politician, with his headquarters in a corner whisky shop, has more power with the men whom the people elect than any ten thousand voters." That the latter is literally true seems to be fully substantiated by the fact that the legislature kept on unconcernedly in its disreputable course in the face of the most urgent and indignant protests from vast representative meetings of all the most influential citizens, as well as from the entire press and the entire medical profession of the metropolis, assembled in mass meeting and in the various societies.

At last, in the latter part of May (after the high rate of mortality had still continued as in the earlier months of the year, and after small-pox and typhus fever had both been prevailing for some time), a very poor substitute for the original street-cleaning bill passed the legislature, and has now received the signature of the governor. There is no occasion to mention the various provisions of this wretched piece of jobbery here; it is sufficient to refer to the fact that both the mayor and the president of the board of health sent to Albany formal memorials against its becoming a law. The most severe comment that has yet been made upon the disgraceful action of the legislature, however, is found in the letter in which Lieutenant-Commander Goringe, who signified his willingness to accept the position of superintendent of street-cleaning under the provisions of the first bill, has now declined the office tendered him by Mayor Grace under those of the bill that finally passed, which leaves ample opportunity for the same corrupt and fraudulent practices which have so long prevailed in this depart-

ment, and which is altogether likely to result in the streets remaining in the same abominable condition as before. The great defect of the present bill is that it divides the responsibility for cleaning the streets among five departments: the mayoralty, the health department, the police department, the board of estimate and apportionment, and the department of street-cleaning (and thus among ten or twelve officials), while the superintendent, who will have to stand the brunt of public attack if the work is not properly done, has rather less effective power than any one of those among whom the legislature has parceled out the powers which the people of the city demanded should be concentrated upon one man. On the other hand, the one essential provision of the citizens' bill, as it was appropriately called, was that it combined entire control with entire responsibility, and placed them both upon the mayor, who was thus directly answerable to the people for the condition of the streets.

At the mass meeting of physicians held at Chickering Hall, in the month of April, the opinion was expressed in the resolutions that were unanimously adopted on that occasion that the neglect to remove accumulations of filth and garbage from the streets produces disease, renders a simple type of it malignant and dangerous, and acts injuriously in the following ways: (1.) Meats and other food exposed for sale are poisoned by the exhalations from the filth. (2.) The air-boxes of dwellings convey a poisoned atmosphere. (3.) The heavy rains and snow bring into solution the accumulations at the mouths of obstructed culverts, and aggregate and intensify morbid agencies. (4.) The irritating and poisonous dust from excrementitious substances and filth is of the greatest damage to the eyes and the air-passages. (5.) Malaria is created and fostered by the reeking sewers and gutters. (6.) The difficulties of maintaining cleanliness in the house and in the person are greatly increased. (7.) Persons are so disabled by living in the midst of these injurious influences that many are compelled to seek frequent changes of climate. (8.) The children of the poor, who live in tenement houses, under bad sanitary conditions, and attend school in crowded school-houses, have as their only play-ground the streets in which these accumulations from dwellings and from animals are producing their injurious effects. In short, as Dr. Willard Parker, who presided at the above meeting, remarked in the course of his address, no one who breathes such an atmosphere can be looked upon as perfectly healthy. It is true that small-pox, typhus fever, and other infectious diseases have decreased of late, but it is also true that the unusually high death-rate is still maintained as the hot weather comes creeping on, and there is every reason to expect that as the summer advances it will be materially increased, even if there should be no visitation of cholera or yellow fever, which is certainly among the possibilities on account of the presence in the city of so many conditions favorable to the development of disease.

But, of course, unclean streets do not constitute the only source of danger in New York from a sanitary point of view. Among the more obvious additional ones are the overcrowded condition of tenements and school-houses, defective sewerage, and defective house ventilation, drainage, and plumbing. Dr. Day, the sanitary superintendent, has also called attention, in a recent special report to the board of health, to the injurious effect of the scarcity of water upon the public

health. This scarcity began last autumn, and has continued to a greater or less extent to the present time. Its evil effects have been felt less in tenement-houses than in boarding-houses, flats, hotels, and private dwellings not provided with special apparatus for raising the water above the third or even the second floor. These have been pervaded by foul odors, and Dr. Day expresses the opinion that the insufficiently flushed traps and closets have been responsible for much of the sickness of the past season. He concludes his report as follows: "I am informed by the chief engineer of the Croton Aqueduct that it has been running to its full capacity during the winter, and it is evident that the carrying capacity will become less and less adequate as the growth of the city increases the demand for water. The sanitary welfare of the city requires a far more abundant water supply. I would respectfully recommend the introduction of tanks and pumps into houses where in the judgment of the inspectors sanitary considerations demand it." In an exhaustive report on the water supply made in the month of April, Mr. Isaac Newton, chief engineer of the department of public works, states that the city can receive through the present aqueduct no more than it now conveys, and hence, as the population increases, the average supply per head must decrease, and the pressure or height at which water can be delivered to consumers will constantly diminish. The time is not far distant, he says, when the supply will not, in many localities, rise above the basement, while in some situations the water will be almost wholly cut off. The demand, he believes, must be met by the construction of a new aqueduct, and he thinks that it cannot be urged too strongly that a city of such great and constantly increasing magnitude as New York should not rely upon an aqueduct; no other city of equal importance in Christendom being so dependent upon a single engineering structure. On the other hand, Colonel Waring, in his excellent paper on the sanitary condition of New York, published in the May and June number of *Scribner's Magazine*, shows that there is an enormous waste of Croton in the city, and holds that if a complete system of water-meters were introduced, the supply now furnished would be altogether ample for a number of years to come,—the average amount of water to each individual, with the present population, being about eighty gallons per day. Still, there can be no doubt that the present supply will eventually have to be increased, if even the saving recommended could be accomplished; and the matter should receive the most careful attention of the proper authorities at no distant date.

Although the present legislature has been such a disgrace to the State of New York, it has happily not refused to pass the bill requiring the registration of plumbers and the sanitary examination of all new plumbing, mentioned in a recent number of the *JOURNAL*. This will constitute an excellent supplement to the laws already in force providing for the improved construction of tenement and apartment houses; and in the passage of such acts from time to time there is to be found, at all events, some little encouragement for the future. There can be no doubt, also, that during the coming summer a very considerable saving of life will be accomplished by the various facilities for removing infants and young children for longer or shorter periods from the injurious influences of the heated city which have of late years been gradually multiplying.

REPORTED MORTALITY FOR THE WEEK ENDING MAY 28, 1881.

Deaths reported 2571 (no report from Buffalo); 1024 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 663, consumption 389, lung diseases 223, diphtheria and croup 159, scarlet fever 117, diarrhoeal diseases 112, cerebro-spinal meningitis 67, small-pox 61, typhoid fever 12, measles 33, malarial fevers 31, whooping-cough 19, erysipelas seven, puerperal fever seven, typhus fever seven, malignant pustule one. From *cerebro-spinal meningitis*, Chicago 11, New York 13, Milwaukee 11, St. Louis eight, Cincinnati and Pittsburgh four, Brooklyn, Baltimore, Fall River, and Lynn two, Philadelphia, District of Columbia, Charleston, Nashville, and Worcester one. From *small-pox*, Philadelphia 29, New York 15, Chicago 13, Brooklyn and Pittsburgh two. From *typhoid fever*, Philadelphia 19, Chicago nine, Baltimore and Pittsburgh four, New York, Cincinnati, District of Columbia, and Salem two, Boston, St. Louis, Charleston, Worcester, New Bedford, Taunton, and Newburyport one. From *measles*, New York 16, Chicago five, Baltimore and Cincinnati four, Brooklyn, St. Louis, New Orleans and Nashville one. From *malarial fevers*, New York 12, Brooklyn five, New Orleans four, St. Louis three, District of Columbia two, Baltimore, Cincinnati, Milwaukee, New Haven and Charleston one. From *whooping-cough*, Philadelphia seven, Chicago four, New York two, Brooklyn, Boston, Cincinnati, Providence, Lowell, and Cambridge one. From *erysipelas*, New York three, St. Louis two, Philadelphia and Milwaukee one. From *puerperal fever*, New York, Philadelphia, Boston, St. Louis, Cambridge, Lynn, and Waltham one. From *typhus fever*, New York seven. From *malignant pustule*, Amherst one. The mortality from *cerebro-spinal meningitis* has increased from 53 for the week ending May 21st to 67.

Thirteen cases of small-pox were reported in Brooklyn, 29 in Chicago, one in Cincinnati; diphtheria 25, scarlet fever five, typhoid fever two, in Boston; scarlet fever 17, diphtheria 13, in Milwaukee.

In 15 cities and towns of Massachusetts, with a population of 1

1,022,504 (population of the State 1,783,086), the total death-rate for the week was 17.13, against 18.90 and 21.09 for the previous two weeks.

For the week ending May 7th, in 149 German cities and towns, with an estimated population of 7,575,425, the death-rate was 27. Deaths reported 3937; under five 1754; pulmonary consumption 587, acute diseases of the respiratory organs 399, diphtheria and croup 151, diarrhoeal diseases 110, scarlet fever 66, typhoid fever 54, whooping-cough 40, measles and röteln 40, puerperal fever 28, typhus fever (Königsberg five, Danzig two, Stettin four, Stralsund, Thorn two, Tilsit, Posen, Magdeburg, Brandenburg, Dessau) 19, small-pox (Königsberg three, Stuttgart, Berlin two, Koburg, Bremen, Aachen two) 10. The death-rates ranged from 16.7 in Metz to 40 in Augsburg; Königsberg 35.1; Breslau 31.7; Munich 31.9; Dresden 27.4; Berlin 23.8; Leipzig 23; Hamburg 27.9; Bremen 28.7; Cologne 28; Frankfurt 19.8; Strasburg 35.3.

For the week ending May 14th in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 20.2. Deaths reported 2944; acute diseases of the respiratory organs (London) 251, measles 114, whooping-cough 74, small-pox (London) 69, 70, scarlet fever 55, diarrhoea 32, fever 27, diphtheria 24. The death-rates ranged from 14.5 in Plymouth to 26.5 in Wolverhampton; Bristol 15.6; Birmingham 17.7; London 20.1; Sheffield 20.7; Liverpool 21; Leeds 22.6; Manchester 22.8. In Edinburgh 21.7; Glasgow 22.3; Dublin 29.9.

In the 21 chief towns in Switzerland, for the week ending May 14th, population 479,934, there were 39 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 14, diphtheria and croup 10, whooping-cough five, measles five, typhoid fever five, small-pox three, scarlet fever one, puerperal fever one. The death-rates were: Geneva 24.3; Zurich 29.4; Basle 31.8; Berne 29.3.

The meteorological record for the week in Boston was as follows:—

Deaths reported 2369 (no report from New Orleans or Buffalo); 913 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 619, consumption 344, lung diseases 218, diphtheria and croup 158, scarlet fever 102, diarrhoeal diseases 94, small-pox 57, cerebro-spinal meningitis 56, measles 39, typhoid fever 36, malarial fevers 29, puerperal fever 18, erysipelas 14, whooping-cough 11, typhus fever five. From small-pox, Philadelphia 27, New York 20, Chicago eight, Brooklyn and Fall River one. From cerebro-spinal meningitis, Chicago 13, New York 12, St. Louis 11, Cincinnati four, Pittsburgh three, Baltimore, Milwaukee, New Haven and

Fall River two, Philadelphia, District of Columbia, Providence, Somerville, and Westborough one. From measles, New York 20, Chicago five, Brooklyn and Cincinnati three, Boston and Baltimore two, Pittsburgh, Milwaukee, Providence, and Woburn one. From typhoid fever, Chicago 11, Philadelphia six, New York five, Brooklyn, Boston, St. Louis, Cincinnati, Pittsburgh, and Lowell two, Baltimore and Salem one. From malarial fevers, New York 12, St. Louis five, Brooklyn and Chicago three, Philadelphia and New Haven two, Baltimore and Springfield one. From puerperal fever, New York nine, Philadelphia three, District of Columbia two, Boston, St. Louis, New Haven, and Holliston one. From erysipelas, Philadelphia four, Cincinnati

three, New York two, Chicago, Baltimore, District of Columbia, Lowell, and Fall River one. From *whooping-cough*, Philadelphia, Chicago, Baltimore, and Cincinnati two, New York, St. Louis, and Providence one. From *typhus fever*, New York five.

Twenty-four cases of small-pox were reported in Brooklyn, nine in Chicago, six in Pittsburgh, one in New Haven, seven in Fall River; diphtheria 25, scarlet fever seven, typhus fever two, in Boston; scarlet fever 23, diphtheria ten, in Milwaukee.

In 44 cities and towns of Massachusetts, with a population of 1,092,071 (population of the State 1,783,086), the total death-rate for the week was 17.62, against 17.13 and 18.90 for the previous two weeks.

For the week ending May 14th, in 149 German cities and towns, with an estimated population of 7,736,432, the death-rate was 25.3. Deaths reported 3767; under five 1624; pulmonary consumption 590, acute diseases of the respiratory organs 392, diphtheria and croup 128, diarrhoeal diseases 111, scarlet fever 77, typhoid fever 47, measles and *rubella* 38, whooping-cough 36, typhus fever (Königsberg nine, Danzig three, Stettin two, Thorn, Stolp, Posen, Erfurt two, Berlin, Potsdam) 21, puerperal fever 19, small-pox (Königsberg five, Beuthen, Mu-

nich, Berlin three, Charlottenberg, Aachen three, Essen two) 16. The death-rates ranged from 10.4 in Wiesbaden to 40 in Augsburg; Königsberg 39.5; Breslau 29.5; Munich 35.7; Dresden 20.5; Berlin 22.1; Leipzig 18.2; Hamburg 24; Hanover 13.5; Bremen 31.1; Cologne 29.2; Frankfurt 22.

For the week ending May 21st, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 20.8. Deaths reported 3036: acute diseases of the respiratory organs (London) 256, small-pox (London 103) 104, whooping-cough 94, measles 88, scarlet fever 57, fever 33, diarrhoea 28. The death-rates ranged from 13.3 in Hull to 25.7 in Oldham; Leeds 16.3; Bristol 18.3; Sheffield 20; Birmingham 20.4; London 20.9; Manchester 24.9; Liverpool 25.5. In Edinburgh 18.8; Glasgow 20.6; Dublin 25.2.

In the 21 chief towns in Switzerland, for the week ending May 21st, population 479,934, there were 36 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 19, diphtheria and croup 11, measles 11, typhoid fever five, small-pox two, whooping-cough one. The death-rates were: Geneva 22.8; Zurich 26.4; Basle 26.8; Berne 37.5; St. Imier 58.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 28, 1881, TO JUNE 10, 1881.

BAILY, E. I., lieutenant-colonel and surgeon. So much of paragraph 1, S. O. 112, C. S., A. G. O., as directs him to report to the commanding general, Division of the Pacific, for duty as medical director of the Department of California, is revoked. S. O. 121, A. G. O., May 27, 1881.

CORLES, E., captain and assistant surgeon. Assigned to temporary duty as post surgeon at Fort Verde, A. T. S. O. 56, Department of Arizona, May 20, 1881.

BAILY, E. I., lieutenant-colonel and surgeon. Having reported at division headquarters, in compliance with S. O. 112, paragraph 1, C. S., A. G. O., is assigned to duty in San Francisco as attending surgeon, relieving Surgeon C. C. Keeney. G. O. 10, Division of the Pacific and Department of California, May 31, 1881.

CONSON, J. K., captain and assistant surgeon. Granted leave of absence for one month, with permission to apply for two months' extension. S. O. 61, Department of Arizona, May 31, 1881.

HELMANN, C. L., captain and assistant surgeon. The telegraphic instructions of 25th inst. to commanding officer, Fort Townsend, W. T., directing Assistant Surgeon Helmann to report at these headquarters, continue in force. S. O. 71, Department of California, May 21, 1881.

ANSON, F. C., captain and assistant surgeon. Relieved from temporary duty at post of San Antonio, Texas, and assigned to duty at Fort Clark, Texas. S. O. 76, Department of Texas, May 31, 1881.

SCHULTZ, R. W., first lieutenant and assistant surgeon. Assigned to temporary duty in the surgeon-general's office. S. O. 120, A. G. O., June 7, 1881.

PERLEY, H. O., first lieutenant and assistant surgeon. Relieved from duty in Department of Dakota, and to comply with S. O. 104, C. S., A. G. O. S. O. 97, Department of Dakota, June 6, 1881.

POWELL, J. L., first lieutenant and assistant surgeon. Relieved from duty with Co. A, 22d Infantry, on arrival at Fort Concho, then to proceed to Fort Stockton, Texas, and report to post commander for duty as post surgeon. S. O. 76, C. S., Department of Texas.

BENHAM, R. B., first lieutenant and assistant surgeon. Relieved from duty at Fort A. Lincoln, D. T., and assigned to duty at Fort Assiniboine, Mont. T. S. O. 97, Department of Dakota, June 6, 1881.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting of the society will be held on Monday evening, June 20th, at eight o'clock, at the hall of the Medical Library Association, 19 Boylston Place. Reader, Dr. Ingalls. Subject, Headache. M. H. RICHARDSON, M. D., Secretary.

GYNÆCOLOGICAL SOCIETY OF BOSTON.—Next stated meeting will be held first Thursday of July, at 10.30 o'clock A. M. Paper by T. M. Durell, M. D. Subject, Functional Nervous Diseases depending upon Uterine Disease. Profession cordially invited. HENRY M. FIELD, M. D., Secretary.

AMERICAN NEUROLOGICAL ASSOCIATION.—The seventh annual meeting of the association will be held in New York on June 15th, 16th, and 17th, at the Academy of Medicine, No. 12 West Thirty-First Street. The profession are invited to attend.

POEM WRITTEN BY DR. OLIVER WENDELL HOLMES FOR THE CENTENNIAL ANNIVERSARY DINNER OF THE MASSACHUSETTS MEDICAL SOCIETY, JUNE 8, 1881, AND READ BY HIM ON THAT OCCASION.

[Dr. HOLMES said on rising:]

IN speaking of some of the trials to which the members of the three "learned professions" are exposed, I have not hesitated to emphasize those specially belonging to the Medical Profession. I owe to my friends the Physicians so much more than the practice of medicine owes to me that I feel at liberty to praise their calling without reserve, but no more than I think its due.

THREE paths there be where Learning's favored sons,
Trained in the schools which hold her favored ones,
Follow their several stars with separate aim;
Each has its honors, each its special claim.
Bred in the fruitful cradle of the East,
First, as of oldest lineage, comes the Priest;
The Lawyer next, in wordy conflict strong,
Full armed to battle for the right,—or wrong;
Last, he whose calling finds its voice in deeds,
Frail Nature's helper in her sharpest needs.
Each has his gifts, his losses and his gains,
Each his own share of pleasures and of pains;
No life-long aim with steadfast eye pursued
Finds a smooth pathway all with roses strewed;
Trouble belongs to man of woman born,—
Tread where he may, his foot will find its thorn.

Of all the guests at life's perennial feast,
Who of her children sits above the Priest?
For him the brodered robe, the carven seat,
Pride at his beck, and beauty at his feet,
For him the incense fumes, the wine is poured,
Himself a God, adoring and adored!
His the first welcome when our hearts rejoice,
His in our dying ear the latest voice,
Font, altar, grave, his steps on all attend,
Our staff, our stay, our all but Heavenly friend!
Where is the meddling hand that dares to probe
The secret grief beneath his sable robe?
How grave his port! how every gesture tells
Here truth abides, here peace forever dwells;
Vex not his lofty soul with comments vain;
Faith asks no questions; silence, ye profane!
Alas! too oft while all is calm without
The stormy spirit wars with endless doubt;
This is the mocking spectre, scarce concealed
Behind tradition's bruised and battered shield.
He sees the sleepless critic, age by age,
Scrawl his new readings on the hallowed page,
The wondrous deeds that priests and prophets saw
Dissolved in legend, crystallized in law,
And on the soil where saints and martyrs trod
Altars new builded to the Unknown God;
His shrines imperilled, his evangels torn,—
He dares not limp, but ah! how sharp his thorn!
Yet while God's herald questions as he reads
The outworn dogmas of his ancient creeds,
Drops from his ritual the exploded verse,
Blots from its page the Athanasian curse,
Though by the critic's dangerous art perplexed,
His holy life is Heaven's unquestioned text;
That shining guidance doubt can never mar,—
The pillar's flame, the light of Bethlehem's star!

Strong is the moral blister that will draw
Laid on the conscience of the Man of Law
Whom blindfold Justice lends her eyes to see
Truth in the scale that holds his promised fee.

What! Has not every lie its truthful side,
 Its honest fraction, not to be denied?
Per contra,—ask the moralist,—in sooth
 Has not a lie its share in every truth?
 Then what forbids an honest man to try
 To find the truth that lurks in every lie,
 And just as fairly call on truth to yield
 The lying fraction in its breast concealed?
 So the worst rogue shall claim a ready friend
 His modest virtues boldly to defend,
 And he who shows the record of a saint
 See himself blacker than the devil could paint.

What struggles to his captive soul belong
 Who loves the right, yet combats for the wrong,
 Who fights the battle he would fain refuse
 And wins, well knowing that he ought to lose,
 Who speaks with glowing lips and look sincere
 In spangled words that make the worse appear
 The better reason; who, behind his mask
 Hides his true self and blushes at his task,—
 What quips, what quillets cheat the inward scorn
 That mocks such triumph? Has he not his thorn?

Yet stay thy judgment; were thy life the prize,
 Thy death the forfeit, would thy cynic eyes
 See fault in him who bravely dares defend
 The cause forlorn, the wretch without a friend?
 Nay, though the rightful side is wisdom's choice
 Wrong has its rights and claims a champion's voice;
 Let the strong arm be lifted for the weak,
 For the dumb lips the fluent pleader speak;—
 When with warm "rebel" blood our street was dyed
 Who took, unawed, the hated hirelings' side?
 No greener civic wreath can Adams claim,
 No brighter page the youthful Quincy's name!

How blest is he who knows no meaner strife
 Than Art's long battle with the foes of life!
 No doubt assails him, doing still his best,
 And trusting kindly Nature for the rest;
 No mocking conscience tears the thin disguise
 That wraps his breast, and tells him that he lies.
 He comes; the languid sufferer lifts his head
 And smiles a welcome from his weary bed;
 He speaks; what music like the tones that tell
 "Past is the hour of danger,—all is well!"

How can he feel the petty stings of grief
 Whose cheeting presence always brings relief?
 What ugly dreams can trouble his repose
 Who yields himself to soothe another's woes?

Hour after hour the busy day has found
 The good physician on his lonely round;
 Mansion and hovel, low and lofty door,
 He knows, his journeys every path explore,—
 Where the cold blast has struck with deadly chill
 The sturdy dweller on the storm-swept hill,
 Where by the stagnant marsh the sickening gale
 Has blanched the poisoned tenants of the vale,
 Where crushed and maimed the bleeding victim lies,
 Where madress raves, where melancholy sighs,
 And where the solemn whisper tells too plain
 That all his science, all his art, were vain.

How sweet his fireside when the day is done
 And cares have vanished with the setting sun!
 Evening at last its hour of respite brings
 And on his couch his weary length he flings.
 Soft be thy pillow, servant of mankind,
 Lulled by an opiate Art could never find;
 Sweet be thy lumber,—thou hast earned it well,—
 Pleasant thy dreams! Clang! goes the midnight bell!

Darkness and storm! the home is far away
That waits his coming ere the break of day;
The snow-clad pines their wintry plumage toss,—
Doubtful the frozen stream his road must cross;
Deep lie the drifts, the slanted heaps have shut
The hardy woodman in his mountain hut,—
Why should thy softer frame the tempest brave?
Hast thou no life, no health, to lose or save?
Look! read the answer in his patient eyes,—
For him no other voice when suffering cries;
Deaf to the gale that all around him blows,
A feeble whisper calls him,—and he goes.

Or seek the crowded city,—summer's heat
Glares burning, blinding, in the narrow street,
Still, noisome, deadly, sleeps the envenomed air,
Unstirred the yellow flag that says "Beware!"
Tempt not thy fate,—one little moment's breath
Bears on its viewless wing the seeds of death;
Thou at whose door the gilded chariots stand,
Whose dear-bought skill unclasps the miser's hand,
Turn from thy fatal quest, nor cast away
That life so precious; let a meaner prey
Feed the destroyer's hunger; live to bless
Those happier homes that need thy care no less!

Smiling he listens; has he then a charm
Whose magic virtues peril can disarm?
No safeguard his; no amulet he wears,
Too well he knows that Nature never spares
Her truest servant, powerless to defend
From her own weapons her unshrinking friend.
He dares the fate the bravest well might shun,
Nor asks reward save only Heaven's "Well done!"

Such are the toils, the perils that he knows,
Days without rest and nights without repose,
Yet all unheeded for the love he bears
His art, his kind, whose every grief he shares.

Harder than these to know how small the part
Nature's proud empire yields to striving Art;
How, as the tide that rolls around the sphere
Laughs at the mounds that delving arms uprear,—
Spare some few roods of oozy earth, but still
Wastes and rebuilds the planet at its will,
Comes at its ordered season, night or noon,
Led by the silver magnet of the moon,
So life's vast tide forever comes and goes,
Unchecked, resistless, as it ebbs and flows.

Hardest of all, when Art has done her best,
To find the cuckoo brooding in her nest;
The shrewd adventurer, fresh from parts unknown,
Kills off the patients Science thought her own,
Towns from a nostrum-vender get their name,
Fences and walls the cure-all drug proclaim,
Plasters and pads the willing world beguile,
Fair Lydia greets us with astringent smile,
Munchausen's fellow-countryman unlocks
His new Pandora's globule-holding box,
And as King George inquired with puzzled grin
"How—how the devil get the apple in?"
So we ask how,—with wonder-opening eyes,—
Such pygmy pills can hold such giant lies!

Yes, sharp the trials, stern the daily tasks
That suffering Nature from her servant asks;
His the kind office dainty menials scorn,
His path how hard,—at every step a thorn!
What does his saddening, restless slavery buy,
What save a right to live, a chance to die,—
To live companion of disease and pain,
To die by poisoned shafts untimely slain?

Answer from hoary eld, majestic shades, —
 From Memphian courts, from Delphic colonnades,
 Speak in the tones that Persia's despot heard
 When nations treasured every golden word
 The waudering echoes wafted o'er the seas
 From the far isle that held Hippocrates;
 And thou, best gift that Pergamus could send
 Imperial Rome, her noblest Caesar's friend,
 Master of masters, whose unchallenged sway
 Not bold Vesalius dared to disobey;
 Ye who while prophets dreamed of dawning times
 Taught your rude lessons in Salerno's rhymes,
 And ye, the nearer sires, to whom we owe
 The better share of all the best we know,
 In every land an ever-growing train,
 Since wakening Science broke her rusted chain, —
 Speak from the past, and say what prize was sent
 To crown the toiling years so freely spent!

List while they speak :

In life's uneven road
 Our willing hands have eased our brothers' load;
 One forehead smoothed, one pang of torture less,
 One peaceful hour a sufferer's couch to bless,
 The smile brought back to fever's parching lips,
 The light restored to reason in eclipse.
 Life's treasure rescued like a burning brand
 Snatched from the dread destroyer's wasteful hand, —
 Such were our simple records day by day,
 For gains like these we wore our lives away.
 In toilsome paths our daily bread we sought,
 But bread from Heaven attending angels brought;
 Pain was our teacher, speaking to the heart,
 Mother of pity, nurse of pitying art;
 Our lesson learned, we reached the peaceful shore
 Where the pale sufferer asks our aid no more, —
 These gracious words our welcome, our reward,
 Ye served your brothers; ye have served your Lord!

MEDICAL SOCIETIES: THEIR ORGANIZATION AND THE NATURE OF THEIR WORK.

BY J. COLLINS WARREN, M. D.

The fundamental idea which brought about the formation of the American Medical Association was the improvement of our system of education.¹ During the fifteen years intervening between 1830 and 1845 the number of medical colleges in the United States more than doubled. The competition was great, and short courses of instruction and easy terms of graduation were consequently the rule. Sixteen weeks were very generally adopted as the length of the college term, and in some of the schools it was reduced to thirteen. At the meeting of the Medical Society of the State of New York in 1839, when the subject of medical education was brought forward, it was proposed to hold a national medical convention in Philadelphia the following year, consisting of delegates from the societies and schools of the different States. No response was made to the action of the society. In 1844 the New York society made a second movement in this direction. Dr. N. S. Davis, a delegate from Broome County, New York, offering a resolution that a national convention be called to meet in New York in 1846, the organization of which was intrusted to a

committee, of which Dr. Davis was chairman. On this occasion there was a general response from all quarters except Philadelphia and Boston. The proposed convention assembled in May, 1846, and Dr. Jonathan Knight, of New Haven, was chosen president. Committees were appointed, and resolutions in favor of the formation of a national association and elevation of the standard of medical education were adopted. The convention reassembled the following year, and, after listening to the reports of their committees, resolved itself into the American Medical Association, and elected Dr. Nathaniel Chapman, of Philadelphia, its first president. The two systems discussed at this meeting as the basis of membership were, first, "the delegate," which has since become so familiar to American physicians, and which was adopted; and, secondly, that proposed by Dr. Isaac Hays, which contemplated an organization, the members of which should be elected by itself, either directly or through a board of councilors, thereby making it independent of state and local societies and institutions. It was thought that the latter plan would give the Association greater stability, and make membership more select and permanent, while it was argued that the former would give the Association more influence among the profession at large, and would favor the development of state, county, and city societies throughout the Union. The delegate system was adopted; but finally, in 1871, delegates from hospitals and col-

¹ *Collegium Medicum*, p. 426-448.

² *History of the American Medical Association*. By N. S. Davis, M. D., Philadelphia, 1856.

leges were excluded, the State and county societies, which are recognized by their own State society, alone being represented. Even this modification does not seem to have proved very satisfactory, for in 1877 it was proposed by the president, Dr. Bowditch, that every member of a State society should be *ex officio* a "permanent member," the number of delegates being greatly reduced. But this plan was objected to, a committee subsequently reporting that it would be desirable if uniformity of organization and the payment of fees could be secured. It is interesting in these early meetings to note the character of the resolutions bearing upon medical education, having in view increase in the length of term,¹ the necessity of a full three years' course of study, a higher and more uniform standard of preliminary education, and the separation of the teaching from the licensing power.

A prominent feature of these meetings was reports from standing committees on medical science, on practical medicine, on surgery, on obstetrics, on medical education, on medical literature, and on publication. At the second meeting in Baltimore the report of Dr. Holmes on medical literature justly criticised the proneness of American writers of that period to content themselves with the position of editors of foreign works, and the character of our periodical literature, and urged the substitution of original for parasitical authorship. The beneficial effect of such criticisms from the Association is indicated by Dr. Davis, in his presidential address in 1865. When the Association was formed publishers would not take books from American authors. The influence of the Association had, he thought, already at that time wrought an entire change. The second annual meeting was held in Boston, and Dr. John C. Warren was elected the third president. It is particularly worthy of note at the present time that in connection with the report of the committee on medical education a paper was presented from the faculty of Harvard University *opposing* the proposition to extend the annual college terms to six months. It was at this meeting that social features were introduced, an entertainment being offered to the Association by the physicians of Boston.

Already at the third meeting an interest in public hygiene began to manifest itself, and papers on subjects pertaining thereto were offered from Boston, New York, and New Orleans. An appropriation having been made for two annual prizes, the first was awarded at the fourth meeting, in Charleston, in 1851, "to Dr. John C. Dalton, Jr., for the Essay On the Corpus Luteum of Menstruation and Pregnancy."

The annual reports of committees, containing abstracts which were lengthy and uninteresting, were soon abolished, the number of committees being enlarged to thirty, and special subjects being assigned to each.²

At the next meeting we find the Association memorializing Congress in regard to abuses in the merchant marine, and as early as 1852 the propriety of substituting a periodical journal for the Transactions was suggested by Dr. J. B. Flint, of Kentucky. This proposition has been advocated since by Drs. Gross,

Sayre, and Parvin, at different meetings, as it was thought that no other measure would promote so efficiently the prosperity of the Association, and in this view they are undoubtedly correct.

The Association early felt the importance of medical organizations in the different States; but few State societies and smaller local societies had been formed, and the masses of the profession had not only no coherence, but were actually separated.³ A committee was appointed to draw up a plan of organization of State and county societies, for the purpose of facilitating and encouraging such formation. It was suggested in the report that the counties should be made "auxiliary" to the State, and the State societies "auxiliary" ⁴ to the national association. As the importance of maintaining a high standard of education was not forgotten, each State was strongly urged to include in their plan the formation of a board of Censors. It was contemplated that the counties should send in reports from its individual members to the State, and the States in their turn should make return to the parent society, thereby establishing a concert of action throughout the country.⁵

Dr. Chaillé says in regard to this point: "In fine, the most important duty of this association is to devise ways and means to organize the medical profession in county societies, to gather these into State societies, and to aggregate the whole into this Association, and to induce each physician to contribute \$10 to \$15 to support the three societies. The Association would thus obtain a revenue of \$200,000." Such a plan, attractive as it may appear, would be impracticable at the present time. It would be difficult to collect fees or to persuade members to take an active interest, judging from the experiences of State societies. For instance, in 1878 Georgia dropped 300 of 547 members for non-payment of fees.

The code of the committee referred to above did not prove satisfactory, for we find Drs. Gross and Davis stating, in 1878, that many of the State societies were little more than annual mass-meetings, and that there was no uniformity in the plans of organization.

It has been proposed since to improve upon the old code, and to publish in the Transactions annually a statistical report of certain specified details for every State society; also, peculiarities of its regulations, or measures it is using to promote its efficiency. The State societies have also been requested to publish a register of the members of the profession in good standing. No society, however, has complied, although many local registers are published.

The plan of committees to report on special subjects proving a failure, all special work was, in 1860, referred to the "sections," which by holding simultaneous meetings accomplish a far greater amount of work.

The next great improvement in organization was effected in 1873, when the formation of a judicial council satisfactorily disposed of what was becoming a great source of annoyance and impediment to work,—the discussion of local questions of ethics at the general meetings. The council consists of twenty-one members, seven new members being added each year, and seven retiring.

¹ The University of Pennsylvania extended its lecture term to six months, and the College of Physicians and Surgeons lengthened its course to five months. Other schools added a few weeks to the term, but this was all that was accomplished.

² Somewhat after the plan of the International Congress, above mentioned. The plan did not succeed; not one in six furnished a report of any kind. Dr. Davis, Presidential Address, 1865.

³ Dr. Bowditch, Presidential Address, 1877.

⁴ "Delegated bodies," or independent bodies represented by delegates.

⁵ When the Association was formed there were about 125 societies in the United States. Now there are over 1200.

As in the earlier meetings the presidential addresses teemed with suggestions on the subject of medical education, so in later years we find the growing interest manifested in public hygiene. Since 1870 this has been strongly marked. In 1871 the Association urged that a professorship of hygiene should be established in every medical college, that every State government should be memorialized to establish a board of health, and that members should use their influence to induce Congress to form a national board. In 1873 a section of state medicine and public hygiene was formed. In the Transactions for 1879, the exceedingly valuable and interesting paper by Dr. Chaillé, of New Orleans, on State Medicine and State Medical Societies, and papers on Protective Sanitation, by Dr. Storer, and Registration of Disease, by Dr. Balch, testify to the increased interest in these matters.

The Association does not appear to have taken any stand in regard to the perplexing question of medical license laws in the several States. It seems to have contented itself, and perhaps judiciously so, with recommending the exaction of preliminary education by boards of Censors, and later in advising the societies to examine all practitioners, whether graduates or not; in other words, with urging a high standard of excellence from each State society.

It has used its influence to secure improved rank for medical officers in the army and navy, and its repeated efforts through committees have undoubtedly helped to give us the first volume of the Index Catalogue.

Resolutions have also been passed, having in view the prevention of criminal abortion, and reform in the methods of securing expert testimony.

This brief sketch is sufficient to show the character of the work attempted by the society, and to enable us to estimate roughly what it has accomplished. The medical mind throughout the country was roused into activity by its formation.¹ Although the early work in aid of medical education had little apparent effect at the time, undoubtedly it may fairly claim a share of the influence which has brought about the great changes of the last decade. The questions of public health, which have lately been so prominent, have reminded us of the usefulness of such a body, when well managed, in time of need. The result is certainly more satisfactory than one might have expected, considering its diminished popularity in the Eastern and Middle States² during the last ten or fifteen years of its existence. The class of medical men who take an active part in the work of the Association are no longer of the same stamp as those who attended the meetings in the early years of its life. But comparatively few of the prominent men of the country are now to be seen at the annual gatherings. The causes of this decline it is not difficult to find. The delegate system of membership, which was not adopted without opposition, seems largely to blame for this unfortunate result, offering, as it does, but little inducement for membership, and opening the door to any one who may wish to make this an excuse for a pleasure trip, or who may desire to use the Association as a means of personal aggrandizement. The ever-changing character of the material of this body gives it a lack of stability and permanency which must necessarily greatly impair its efficiency. The conditions which exist in this country

are to be met only by an organization specially devised for the purpose, and it would clearly be impossible to select any other national association for a model. The lack of uniformity in our State societies would prevent, for instance, the adoption of so simple a plan as that of the British Medical Association. In 1872 this question was freely discussed in the medical journals, and amongst other plans it was proposed to establish a national council,³ a sort of medical senate, the members of which were to be elected for a term of years by State councils, whose members in turn should be selected from congressional districts. To such a body would be intrusted the scientific and professional business of the Association. Eventually, the various State and county societies might be included as branches and sub-branches of the parent society. An important element in the success of any such large body of medical men is the inducements which it offers to each individual to become a member. He must see a substantial return for the money annually paid in assessments. The sum is usually larger than the average practitioner can afford to spend for objects the usefulness of which may appear to him somewhat remote. The annual volume of Transactions does not supply this need. The work of the annual meeting does not appear until many of the questions it has discussed have, in these rapidly-moving times, lost the vitality which made them topics of special interest at the moment. During the greater part of the year the Association is a blank; beyond the feeble efforts of a few committees, its work seems to have come to a stand-still. Nothing is known of the coming meeting by the profession at large. Contrast this fact with the methods adopted by the International Congress; how much more we know about a meeting which is to take place three thousand miles away than we did beforehand of one which has taken place at our very doors! The publication of a weekly periodical would not only fill this void for each individual, but would be a powerful incentive to the Association for continuous work throughout the year. This would of course necessitate a radical change in the organization of the society, which is perhaps the reason why its leaders have shrunk from taking the step.

The future of the Association depends largely upon the success with which it identifies itself with the interests of the State societies. It should become a bond of union between them, the usefulness of which should be made so apparent that all would be glad to avail themselves of it. To effect this object, the present organization must be discarded, and an active and vigorous body must take its place, making its influence perennial, and appropriating for its highest offices the ablest men in the country. With such machinery the profession of the United States would, I think, be started to find the power which it would be able to exert.

The Medical Association of the State of Alabama was organized in 1818, and reorganized in 1873.

The objects of the Association are stated to be the organization of the medical profession of the State in the most efficient manner; to encourage a high standard of medical education, and regulate the qualifications of practitioners of medicine; to watch over and protect all the interests of the medical profession of the State; and to supervise the sanitary laws and interests.³

¹ Dr. Gross, Presidential Address, 1866.
² Dr. Bowditch, Presidential Address, 1877.

³ Boston Medical and Surgical Journal, July 25, 1872.

⁴ The composition of the society is somewhat complicated, the

The peculiar features of this Association are the attitude which it has assumed towards the regulation of the practice of medicine and its public health system. The various boards of Censors assume the double duties of examining boards and boards of health for the State at large, and for its various counties respectively.

The draft of an act to regulate the practice of medicine was submitted to the Association in 1871, and became a law in 1877, after an active opposition in the Legislature. The leading features of this law are as follows: The State and county boards of Censors are constituted boards of medical examiners, from whom all persons intending to practice medicine in the State must obtain a certificate of qualification after passing an examination. All persons legally engaged in practice at the time of the passage of the law are continued in the enjoyment of their rights under certain regulations. It has been found expedient not to molest any practitioner actually in practice at that time, even though he be thus engaged without the authority of the law, except in notorious cases. The examinations for those who propose to practice the "regular" system of medicine include anatomy, physiology, elements of chemistry, organic and inorganic, materia medica, therapeutics, pathology, theoretical and practical medicine, surgery, obstetrics, hygiene, and medical ethics.

Those who propose to practice some irregular system are examined only in chemistry, anatomy, physiology, and the mechanism of labor. The examinations are partly oral and partly written.

There are preliminary examinations laid down for those who intend to begin the study of medicine, which include English grammar and literature, outlines of history, elements of arithmetic, algebra, geometry, physics, or natural philosophy.¹

The certificate of the board is duly registered in the probate court of the county. After having passed the examination, the successful candidate, if a "regular," is generally elected into the county society. Up to the present time the county boards have been engaged for the most part in the preliminary work of issuing *pro forma* certificates to those already engaged in the practice of medicine. They have also made a few examinations of applicants who propose to practice the regular system of medicine. Practitioners of the peripatetic class have as a rule declined to come before the

boards, when summoned to do so, and have preferred rather to leave the State. Numerous cases of this kind have occurred. The penalty for violation of the law is a fine not exceeding one hundred dollars, and in default of payment imprisonment for not over one year.

In one of the reports of the Censors regret is expressed that provision requiring the examination of irregular practitioners has been introduced, as it thus elevates irregular medicine into a position of quasi-respectability, and "because it will, perhaps, give a somewhat longer lease of life to systems of practice that are already falling into decay, and that should have been allowed to die as quietly as possible, without being temporarily galvanized into an appearance of vitality by legislative action."

The Association has in view the annual publication of a complete register of medical practitioners of the States.²

The State Association is also made the State Board of Health, and the functions of county boards of health are invested in the several county medical societies, "thus virtually engaging all the doctors of the State in the sanitary service of the people, and in the administration of the health laws of the State." The bill proposing this measure was passed in 1875. In 1879 an act was passed appropriating three thousand dollars for the use of the State Board. The county boards enjoy only advisory powers, and are conducted without expense to the State. Under certain emergencies they may be invested with extra powers and duties by the legal authorities.

It is proposed to pass an act this year to provide for the supervision of the public health, and for the collection of vital statistics. The act specifies more accurately the duties of the various boards, including the supervision of all public institutions, and all matters pertaining to quarantine and quarantine physicians.³ Each county board has a health officer at a salary of not less than one hundred dollars a year, who is the executive officer of the board. He attends to all the specified duties, is prepared to vaccinate and perform any additional duties which may be assigned him. He must keep a register of births and deaths and infectious diseases, and every physician, midwife, or citizen is expected to send to him full reports. He is obliged to make weekly, monthly, and annual reports to his board of all business done in connection with his office, and the county boards make to the State Board an annual report, "containing all the vital and sanitary statistics of the county," and any other information that may be deemed advisable. The health officer may have assistant health officers appointed to aid him in this work. Fines may be inflicted to compel information upon the desired points. The State Board can declare quarantine measures when thought necessary, and twenty thousand dollars are annually appropriated for quarantine purposes. This board may also have its health officer, if deemed important. His term of service lasts five years, and he is paid out of the annual appropriation first mentioned. His business is to

members of the Association being divided into four classes, namely, members, delegates, councilors, and correspondents. The members of county societies are "members" who have the privilege of attending the sessions of the general society, but are not allowed to vote. Two "delegates" are chosen annually by each county to represent them in the Association. They are entitled to vote on all questions which come before the Association, but cannot hold office. The "councilors" are a body of one hundred members, formed from some preëxisting body, apparently. They hold their positions permanently, and vacancies are filled by a joint vote of councilors and delegates. "Correspondents" are honorary members. The board of Censors of the Association consists of ten men, elected for such terms that there shall be two vacancies annually to fill. They act as a general committee of reference in all questions relating to the organization and general welfare of the Association, and have other peculiar functions, presently to be mentioned. The county societies have each a body of Censors consisting of three members. The annual meeting is on the first Tuesday in April, and lasts four days. Thirty-two county societies have been organized, containing 382 members. Members pay a fee of one dollar. Delegates pay a fee of five dollars. Councilors pay a fee of ten dollars. Each member pays to the county society five dollars annually. "None of the funds of the Association shall ever be appropriated to furnishing festivals or entertainments; nor for any purpose whatever except such as may look directly to the advancement of medicine, including under this head the publication of an annual volume of Transactions."—Constitution M. A. A., Sec. XII.

¹ No practitioner can receive a student who has not passed the preliminary examination.

² The county societies are held strictly to account, and may be censured, or their charter may be forfeited to the general society.

³ It is also specially provided "that no person laboring under any pestilential or infectious disease shall come or be brought into any such county, or removed from place to place, except by permission of the county board of health," and "that no dead human body shall be brought into any such county or removed from place to place," etc.

conduct the correspondence of the State Board, to assist in organizing and conducting the county boards, and to take charge of the annual reports.¹

Ordinances exist also for the regulation of the practice of pharmacy and the practice of dentistry in the State. Attention should be called to an important recommendation in the last report of the Censors, "that no laws affecting the interests of the medical profession in any way should be allowed to go before the General Assembly without first having received the indorsement of the Association."

In the Transactions for 1875 we notice the following significant remark: "We will appreciate most adequately the real character of the Association if we regard it as a medical legislature, having for its highest function the governmental direction of the medical profession of the State, while its other functions, important as they are in themselves, are, in comparison with this, of quite subordinate rank."

Undoubtedly the work to be performed by this very energetic body will produce satisfactory results, and the plan may prove the one best adapted to the present needs of the State, being perhaps the most effective that could be devised for inculcating a due appreciation of the laws of public hygiene and raising the standard of the profession in Alabama. The experiment of such a species of medical legislature should be watched with interest by the profession, as whatever may be its fate its experiences will be most instructive to similar bodies throughout the country.

The Medical Society of the State of North Carolina has an organization similar to that of Alabama.² By an act passed in 1877 the society was constituted the State Board of Health, the county societies becoming the boards of health for the various counties, under the direction of the general board; these boards receiving from the competent legal authorities any necessary powers for carrying on their work as may be agreed upon. No other boards are allowed to exist, the object being to secure a uniform system of sanitary supervision throughout the State. The sum appropriated for this work by the Legislature was at first but one hundred dollars, but this has since been increased to two hundred dollars; and it is expected that the State government, having appreciated the great advantages of such an organization to the welfare of the State, will establish it upon a basis more on an equality with other departments, as that of agriculture, as a "health department," with perhaps a "commissioner of health" as a State officer, and that it will become auxiliary, if properly managed, to the Board of Educa-

tion.³ It is stated that the object of this plan is to preserve the board from the contamination and corruption of political parties. In a supplemental act passed in 1879, it was provided that the board should consist of six members elected by the society, and three members, one of whom should be a civil engineer, appointed by the governor.⁴ The board is disposed to cooperate heartily with the National Board of Health. The latest accounts show that the board is actively at work, and endeavoring to organize a system of registration for vital statistics, and to inculcate elementary sanitary principles among the people. The secretary complains of the ignorance of government officials and the indifference of physicians.

An act of 1859 authorized the organization of a board of seven "regularly graduated physicians" under the title of the Board of Medical Examiners of the State of North Carolina, the board to be appointed by the society, unless the Legislature choose to exercise this right, of which it has never availed itself. The term of office is six years. The board meets yearly with the State society, and continues in session until all applicants have been examined, receiving pay for services. Temporary licenses may be granted at other times of the year by any two members of the board. This law, although not making it unlawful for non-licentiates to practice, deprives them of the privilege of collecting fees by legal process. Those practicing at the time of the passage of the act were not affected by it. The law has forced many unwilling physicians to undergo an examination for the license, and many have failed to pass the board.⁵

The Texas State Medical Association was organized in 1869. As is usual in most States, the county societies are represented at the meetings of the State society by delegates, two of whom are chosen for every ten members.⁶ The medical colleges in the State are represented in the society, each school having two votes. There is a council of twenty-one members, to which all questions of an ethical or judicial character are referred. The Association has not succeeded in establishing a State board of health; there is a law authorizing local boards, but it has proved of little value. The chief work has been the establishment of a law regulating the practice of medicine. This was secured in 1873,

¹ Transactions of the Medical Society of the State of North Carolina, 1877. Report of the committee appointed to memorialize the Legislature.

² Those appointed by the society serve two for six years, two for four years, and two for two years; those appointed by the governor serve two for two years. The officers are elected by the board, the president serving two years and the secretary six years. The latter has a salary, the members receiving two dollars a day when on duty. In each county there are provided auxiliary boards, which are composed of members of the county societies, the mayor, the chairman of the county commission, and the city or county surveyor. From this number one physician is elected to serve two years, with the title of superintendent of health, being a salaried officer. His duties are to gather vital statistics, to make medico-legal post-mortem examinations for coroners' inquests, and to attend prisoners in jails, poor-houses, and work-houses. Reports are made and work done as ordered by the State Board. "Inland quarantine" for small-pox, scarlet fever, yellow fever, and cholera is under the control of the county superintendent of health, and any violation of the rules laid down by him subjects the offender to a fine of \$2500 and imprisonment for not longer than twenty days.

³ Dr. L. Julien Picot, the secretary, writes: "Citizens of the State are beginning to demand of their local practitioners that they obtain a license. When a new man settles in a community it is asked of him at once if he had stood and passed his examinations. A diploma counts for nothing now in North Carolina if a man cannot pass the board. Fortunately, we have no 'pathies' as yet in our State." To which might be added: But with returning prosperity and wealth quacks will be probably abound.

⁴ Members pay a fee for the support of the Association. This was reduced in 1878 to fifty cents.

¹ The Board of Health during the past year has memorialized Congress to the effect that the bills now before it to increase the efficiency of the National Board of Health are open to the objection that they give to the National Board the power to establish and administer quarantines within the limits of the State against all commerce and travel of which one of the terminal points lies outside the State, and thus without consent of or consultation with the local authorities. In its opinion the State Board should be required to submit its regulations to the National Board for approval, and if satisfactory proper assistance should be extended to them. The National Board should have general direction and control of quarantine against foreign commerce, but through the agency of the State boards. The memorialists say that the National Board has a wide and important sphere of usefulness, within which local boards have no jurisdiction.

There are permanent members, delegates, associates, and honorary members. The first appear to be members of the county societies, and what counts as members of the Alabama society. "Delegates" are members of the county societies at the general meetings. "Associates" are members of the county societies, and have a right to attend the general meetings, but are not allowed to vote. "Honorary members" are those who are independent of the State society, but may on occasion become "auxiliary" to it.

but has since been modified. It has been framed in accordance with a provision of the constitution of the State that "no preference shall be given by law to any school of medicine." The examining boards, consisting of three practicing physicians, are appointed by judges of the district courts. Every person intending to practice medicine must undergo the examination prescribed by the board. The penalties for non-compliance with this law vary from fifty to five hundred dollars. The licensing power is thus placed entirely under the control of the State. The judges of district courts are supposed to be officers of sufficiently high standing to be intrusted with the formation of efficient boards, although it has been thought by those familiar with the medical acts of other States "that this system offers the best solution of the difficult problems arising from the various divisions of the medical profession." It is stated by Dr. Chaillé that in some districts difficulty has been experienced in organizing the boards owing to the appointment of homeopaths.

The society has interested itself actively in calling the attention of the government to all matters pertaining to state medicine. Unsuccessful efforts have been made to obtain an appropriation for the Galveston Medical College, to enforce compulsory vaccination, to appropriate five thousand dollars for the cultivation of the *Eucalyptus globulus*, etc. In Louisiana an attempt has been made to provide for the maintenance of the University of Louisiana by the State; but in Michigan, where the State society succeeded in establishing a general hospital and a medical department in the University of Michigan, under State patronage, the government appropriated six thousand dollars to support two professorships for teaching homeopathy. Serious and constant trouble has resulted, and advocacy of the doctrine that "a State ought not to establish medical schools, nor support nor govern them."¹

The Illinois State Medical Society possesses many points of peculiar interest. It is one of the oldest of the Western State societies, and was organized in 1850; its secretary, Dr. N. S. Davis, has been more closely identified with society work than any other man in this country, and its relation to the State Board of Health and the medical practice laws present an interesting contrast to those of the societies which have just been described. Of special interest to us is the plan upon which membership is based. Like many of the State societies which followed the pattern of the American Medical Association, the delegate system largely predominated. In addition to delegates, however, "permanent members" were also elected, apparently without any special plan. The consequence was that many men became members who were not in good standing, and many thus elected became alienated from the local societies; others took little interest in the society, and neglected to pay their fees. The feeling became prevalent "that most physicians care nothing for a medical society until sickness, adversity, or a suit for malpractice overtakes them."² The system was evidently an unsatisfactory one and liable to great abuse. It was found necessary to revise the constitution, particularly with reference to the election of members. This was done in 1878. At this time there were but 352 members, and at the annual meeting in 1878 the total attendance was 100 members in a State

where there are 5000 practitioners. In the same year the attendance at the annual meeting of the American Medical Association was 526, and in Maryland, at the meeting of the state society, 150 members were present, being the largest number at any State meeting except that of Massachusetts.

RECENT PROGRESS IN SURGERY.

BY H. H. A. BEACH, M. D.

ANATOMICAL RELATIONS IN TRACHLOTOMY.

THE significance of an abnormally high position of the innominate artery was dwelt upon in a discussion following the reading of a paper before the Medico-Chirurgical Society of Edinburgh by Dr. Symington.³ The author presented a subject in which only half an inch intervened between the artery and the isthmus of the thyroid body, and advocated the employment of a high operation, taking the chances of incising the isthmus of the thyroid gland rather than to incur the increased risk of wounding the artery. Necessarily the risk is more applicable to childhood, but the possibility of such a complication deserves consideration in advising or undertaking the operation.

ECZEMA OF THE NIPPLE AND CANCER OF THE MAMMA. (PAGET'S DISEASE.)

Dr. Thin proposes⁴ to call this affection Malignant Papillary Dermatitis, and concludes that it is "neither eczema nor psoriasis, nor any known specific skin disease." He has observed that "the first change was found at the mouths of the lactiferous ducts from whence it very slowly spread out, and later on formed a cancerous tumor deeply in the mamma; the change in the skin must therefore be cancerous in its nature." The practical conclusion to be drawn from his investigations is, that early excision of the diseased nipple and areola should delay, if not prevent, the gland from becoming involved; on the other hand, Busch, Gross, and Chambers have cured cases by simple local applications without the development of cancer. Evidently, two varieties of disease may attack the nipple and areola; which are so much alike that a prognosis involving the future of the gland proper cannot be safely based upon anything short of a *microscopical* examination of the structures involved; or, it is safe to assume that Paget's disease, as Mr. Erichsen terms it, has a stage when simple means will cure it.

PARTIAL OPERATIONS IN CANCERS OF THE BREAST.

The old question of the local or constitutional origin of cancer was opened by Mr. Lawson in detailing some of his experiences in the cancer wards of the Middlesex Hospital.⁵ He claims that "partial removals of cancerous breasts are not only useless but worse than useless, one operation stimulates the growth of the cancer and hastens the progress of it instead of retarding it. The delay of efficient treatment which such a partial operation causes is very prejudicial, as the recurrence of the disease, which is almost certain to take place, is usually very extensive and frequently such as to forbid any further operative proceedings. In all cases of schirrus of the breast which admit of operation, even though the growth be no larger than a chest-

⁵ Lancet, May 7, 1881.

nut, and be placed at the edge of the gland, the whole breast should be removed and that, rather than perform a partial operation, it is better to allow the disease to run its course."

CANCER OF THE TONGUE.

Vernueil states¹ that "the diagnosis, in a majority of cases, should not be difficult; and, through the recent teaching of M. Fournier, the affection may be readily distinguished from tertiary glossitis. There are hybrid cases where the cancers occur in a subject of old syphilis and in which the objective characters are modified by constitutional treatment, such cases do not require any alteration of treatment, for the hybrid affection in its course, termination, and prognosis resembles pure epithelioma and should be dealt with in like manner. When more than a third of the tongue has been involved or the floor of the mouth is affected, the case cannot be treated by operation with any chance of success. Out of two hundred operations by M. Vernueil, one only was fatal. Operation at an early stage is advised.

ANESTHESIA.

The recent reports of the Scientific Grants Committee of the British Medical Association, composed of pathological, chemical, and physiological experts, and the work of Rottenstein² present strong evidence of the dangers of chloroform as an anæsthetic, and will help to fortify the position so ably held for some years by Mr. Ernest Hart, the editor of the *British Medical Journal*, in advocating the substitution of ether for chloroform as a general anæsthetic.

Mr. H. Macnaughton Jones, surgeon to the Cork County Hospital and Professor of Obstetrics and Gynecology at Queen's College, has published an exceedingly interesting report on anæsthetics, and makes the following epitome of the views now held on the action of chloroform.³

(1.) By chloroform the blood-pressure is "enormously reduced." This fall in the blood-pressure causes an anæmic state of the brain and respiratory centres, which tends to cause ultimately a cessation of respiratory movement and of the heart's action.

(2.) Chloroform produces a paralysis of the inhibitory centres after the primary stimulation.

(3.) Chloroform paralyzes the vaso-motor centres, thus accounting for the fall in pressure.

(4.) Chloroform acts directly on the heart's muscle, destroying its contractile power, and arrests the heart's action suddenly.

(5.) Arrest of respiration may precede stoppage of the heart, or vice versa, dependent, it may be, upon the degree of concentration of the vapor.

Death would appear to occur alike from asphyxia and from syncope, but much more frequently from the latter; in fact, it is doubtful if the cause of death be asphyxia whether we should not look to the method of administration to account for it.

"Si l'on me démontrait l'asphyxie chez un malade mort pendant la chloroformisation, je dirais qu'elle est due à un mode vicieux d'administration." (M. Perrin.) We may conclude that the great cause of death from chloroform is syncope—empty vessels, stoppage of the heart, sudden and often impossible to foresee.

(6.) Chloroform would appear from the researches of some to exercise a direct effect, physically and chemically, upon the blood, altering the size of the corpuscles (contraction), diminishing the amount of carbonic acid, and increasing the oxygen; at the same time the quantity of carbonic acid in the exhaled air is increased.

(7.) Chloroform abolishes conscious sensibility by its action on the perceptive centre, on the cerebral cells themselves,⁴ through their protoplasm⁵ carried thither by the blood, destroying the inherent irritability of the protoplasm, and thus bringing about the disappearance of the sensorial function of consciousness. This liberates the spinal cord to a power of independent action, during which time its reflex functions are exaggerated. Pain is not now felt, analgesia is produced. At the same time the motor brain-cells become affected, and now those of the cord and other tissue elements; finally, in complete anæsthesia, there is perfect muscular relaxation, and should the chloroform be further pressed and attack the medulla, respiration and circulation are arrested—death is the result. Reflex excitability would appear to be first exalted and then a steady lowering to follow in the full stage of anæsthesia. The theory that death may be the consequence of *reflex* stoppage of the heart through the peripheral irritation of the pulmonic nerve is supported by these views of Legroux.⁶ They are more important in their bearing on the action of chloroform during parturition.

Lastly, regarding death from chloroform, it is right to point out: (1) that death frequently occurs after the first few inspirations; (2) that the quantity sufficient to kill varies from a few drops upwards, but that in the majority of cases recorded not more than from one to three drachms have been sufficient to kill; (3) that in a large proportion of cases there is no previous indication of danger—sudden cessation of the pulse and extreme pallor of the face, with alteration in the pupil, being the first indications, these being rapidly followed by an arrest in the respiration; (4) that though abnormal states of the heart—and principally fatty change—have been frequently found after death from chloroform, yet in numbers of other cases the signs are negative, the patients have been in good health, and the heart, lungs, and brain perfectly normal."

PHIMOSIS AS A CAUSE OF HERNIA.

Mr. S. Osborn read a paper before the West Kent Medico-Chirurgical Society recently,⁷ urging *early* circumcision in cases where the prepuce is contracted in order to do away with the strain required to empty the bladder, such straining being one of the common causes of hernia in children, as verified by a large number of observations.

THE ANTISEPTIC SPRAY.

Professor Von Bruns, after trial, has discontinued the use of spray in his surgical operations, on the ground that "the utility and necessity for its employment is not sufficiently proved, and that it must be regarded as a useless addition to the antiseptic treatment. In place of a continuous spray he employs temporary irrigation or watering with a two to five per cent. solution of carbolic acid for a few seconds at a time. In

⁷ *London Medical Record*, March, 1881.

protracted operations the cut surface is washed several times with a two-per-cent. solution of carbolic acid; in other operations this is done at the conclusion only. Moreover, every unhealed surface, if not quite too extensive,—for example, the inner surface of a pleural cavity which has been opened into, or of an abscess which has been evacuated,—is washed out with a stream of carbolic acid solution (five per cent.), and the same proceeding is adopted in amputations after the edges of the flaps have been brought together should any further hemorrhage have occurred, the drainage tubes being employed as the means of access for the carbolized stream."

"In the same way in all dressings of wounds no spray is used, but merely irrigation with a two-per-cent. carbolic acid solution. In other respects the usual rules of the antiseptic treatment are strictly carried out, and especially the use of carbolized gauze, prepared according to my son's method. I regard the dressing of the wound as seldom as possible as of special importance. Thus, after amputations, the first dressing occurs, as a rule, on the eighth, tenth, or twelfth days. In two complete resections of the knee the dressing applied immediately after the operation was not changed until the twenty-eighth day, and not until the thirtieth day in two other cases."

Following the above, the *London Medical Times and Gazette* published an Experimental Inquiry into the Value of the Antiseptic Spray (March, 1881), and concludes that "the antiseptic irrigation of wounds is not only a protective against any possible infection by the air; it fulfills a second and even more important object. It insures the safety of the antiseptics, and this is an object, therefore, which recommends it in all cases, even where the air is not to be feared. The antiseptic treatment requires, comparatively speaking, a complicated apparatus, which must be used with great exactitude, and even with a certain pedantry. The slightest failing may cause the most serious disturbances, and it moreover requires a considerable amount of assistance from others besides the surgeon. Its safety is thus much endangered. Irrigation, on the other hand, is a simple proceeding, and any accidental oversight as regards the fingers, instruments, or sponges is counteracted by efficient irrigation. Then the tissues themselves remain unfavorable to the propagation of bacteria for a considerable time. It is especially during the early hours after an operation that this is of importance, because the tissues themselves are in a condition of what may be termed *local shock*; their function is disturbed by the mechanical result of the operation and the cooling, and they are thus unable for a while to initiate those changes which usher in healing. It may be urged that the irrigation is more irritating, and that it leads to a larger secretion from the wound during the early days after operation; but, although this necessitates more frequent change of dressings, it secures more certain asepsis" . . . "On theoretical grounds it has been shown to be unnecessary, and Trendelenberg and others here, by the result of their operations, show that the spray may safely be dispensed with in practice."

Von Bruns states¹ that during "the two years preceding his publication there were in the hospital sixty-two amputations and disarticulations; ten osteotomies; twenty-six resections of joints; thirteen resections of outside joints; nine trephinnings with scooping out of

flat bones; twenty-four necrothecotomies of long bones. In all one hundred and forty-four operations on bones. Not one of these ended fatally. Besides these one hundred and forty-four operations more than three hundred and fifty other operations were performed in the hospital without reckoning enlargements of wounds, opening of abscesses, and other small incisions.

"The total number of patients admitted to the hospital during these two years was 1175, a number which, with the present accommodation (one hundred beds) was considerably below what it should have been, as the changes which were being made in the hospital caused some reduction in the number of beds in June and July, and the entire closure of the institution in August and September. The deaths among these 1175 patients was 36, a mortality of little more than three per cent., but none of these deaths was due to blood-poisoning, whether pyæmia, septicæmia, or erysipelas.

"These numbers and facts are surely large enough and important enough to inspire even the most ardent supporter of the spray with some doubt as to its necessity, and to induce him to make some experiments in operating and dressing without it."

There can be no question of the disadvantages of operating under the spray and the additional time consumed if it is employed. It is equally true that good results followed certain forms of antiseptic dressing before the days of Listerism, and the special dressings employed by Mr. Lister between the dates of his first paper on the treatment of compound fractures and that wherein he advocated the employment of the spray. But such results could not be expected as surely without the complete dressing as with it, and surgeons have conceded the additional time and annoyance in operating, even in cases where a protracted anæsthesia alone was undesirable for the greater security which the Lister system promised their patients from septic processes.

Therefore, any modifications which do not add to the risks of treatment will commend themselves, and time alone must determine their value. One great disadvantage of irrigation with carbolic acid solutions is the additional opportunity it affords for an absorption of the agent to such a degree as to cause poisonous symptoms or even death. A non-poisonous agent, equally protective, would dispose of this objection. Another is the disturbance of the apposition of wounded surfaces by distention, delaying union and prolonging the treatment. Even Von Bruns insists upon the importance of dressing the wound as seldom as possible.

COD-LIVER OIL.

Mr. R. F. Fairthorne, Ph. G., suggests a new method for the administration of cod-liver oil, which consists in adding about one part of tomato or walnut cats-up to four of the oil, the mixture being well shaken up just before taken. He very pertinently remarks that taking an ordinary emulsion of cod-liver oil is like eating cod-fish or lobster with a dressing of sugar and gum. He has found his suggested mixture to agree much better with many persons than any other form which they have tried. This he attributes to the association of such condiments as are generally employed as additions to food, and which experience has shown best to bring into operation those digestive faculties of the stomach which might otherwise remain dormant. — *American Journal Pharmacy*.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY. — THE CENTENNIAL DINNER.

THE members being assembled about the table, a blessing was asked by the REV. PHILLIPS BROOKS. After showing due appreciation of the provision made for the corporal man, the society was called to order and addressed by the centennial chairman, DR. WHITE, as follows: —

Members of the Massachusetts Medical Society. — It is my pleasant duty, after all these entertainments, during which you have enjoyed the hospitality of a great university, and that extended to you by your fellow members of this society, to welcome you to the closing and best event of all, our annual dinner.

Well may you congratulate yourselves upon this notable birthday of the mother society.

A century of American medicine has passed, and already you have listened to two admirable addresses upon this theme; but I cannot forbear to recall your attention to the possibilities demonstrated in that one hundred years by the progress made in the collateral branches of our art, so richly illustrated in our visit to Cambridge yesterday.

What did those who founded our society know of ethnology, botany, or archaeology? What opportunities did the university offer for the acquirement of such knowledge? Dr. Waterhouse was the first to bring to us some knowledge of these sciences, but not till after the commencement of the present century did we possess any opportunities for their acquirement. In 1814 Dr. Jacob Bigelow published his explorations in this direction, and in the following year was organized a society for the study of natural history, which included, among others, the names of Dr. Walter Channing, George Hayward, John Randall, John Ware, John Warren, Enoch Hall, John C. Warren, and George Shattuck. The magnificent collections that you have recently visited at Cambridge may be proudly claimed to be the legitimate outcome of this early appreciation by those distinguished members of this society for these branches of learning.

With such advances in the past, who will venture to predict what will be taught in the hundred years to come?

Look at the collections of *materia medica* in the adjoining hall, and contrast them with those of a hundred years ago, and who can limit the possibilities of the medical science in 1914?

The hundred years that have passed have been occupied in the development of the race, in active warfare for the defense of all citizens and the encouragement of the highest interests in science and education, and our birthday should well be celebrated as a jubilee, not only by ourselves, but by all who recognize our labors for humanity.

It is, then, with the joyous spirit of the present occasion that we deal to-day.

We have with us the highest representatives of the State, of the university, of divinity, of law, of poetry, and of science. Our sister societies from other States have sent delegates to congratulate us, and eminent physicians from all parts of our country have honored us with their presence.

I beg to offer in conclusion the following sentiment from Dr. Woodard Parker, of New York: 'The Massa-

chusetts Medical Society: As years roll on may she, ever unite with the wisdom and experience of age the vigor and efficiency of youth!' Throughout one hundred years the society has been fortunate in its presidents, from Dr. Holyoke to its present esteemed head. It is fitting that the man who has taken such an active part in its councils should speak for it on its becoming of age. I introduce to you Dr. Henry W. Williams.

DR. WILLIAMS responded as follows: —

Accept my warmest thanks, Fellows of the Massachusetts Medical Society, for this *supreme* honor conferred in my election as your *Centennial* President. I count myself in nothing else so happy as to be thus remembered by my good friends.

The charm of this day is the charm of memory; it brings us face to face with the men of the past. Reading the lesson of the lives of our founders, we find in their high example of honor and faithfulness an inspiration for ourselves. And as we contemplate the eminent and earnest life of our first president, Dr. Holyoke, we may well adopt as our own the yearning invocation of Elisha to the ascending Elijah, "My father, let a double portion of thy spirit fall upon me."

The date of our baptismal certificate, signed by the same bold hand which subscribed the charter of our national liberties, John Hancock, attests for this society a hundred years of honorable life. And though not to many of its Fellows will be accorded the century of usefulness which was granted to the first president of this association, yet, though the members die the society lives.

As I look around me I see a spirit of youth in everything. Our annals are still a record of self-sacrifice, of devotion to duty, of careful scientific research. And as the unit of years since the birth of the society has become a hundred, so the links of the chain of friendship, forged by Holyoke, Rand, Tufts, Warren, and their associates, have been multiplied and strengthened, until it now extends from one extreme of the Commonwealth to the other, from Hoosac's heights to Siasconset's sands, uniting us all in one brotherhood of faith and duty.

But the prophetic eyes of those earnest men, sanguine as they doubtless were, pictured for them no scene like this. The charter of incorporation limited the number of Fellows to seventy, that being as many as it was supposed would in all the Commonwealth be eligible for the honor of admission to such a fraternity. Less than twenty attended at several of the first annual meetings, because, as they said, of the remoteness of their places of residence, Salem and other towns distant from the capital.

Could they revisit us to-day they would surely be satisfied that the seed they had sown in weakness, but in trustful hope, had indeed been raised in power. Could they see what has been done, even in this present generation, by their Massachusetts Medical Society for the promotion of the object so dear to their hearts, as set forth in the charter, the preservation of health, so essential to the happiness of the community; could they behold the veil of unconsciousness softly drawn over the subjects of capital operations, and observe its magic lightening of that pristine sorrow which is forgotten only when a man is born into the world; could they witness the doings of our own great surgeon, Bigelow, who has solved the problem with

which Hippocrates cared not to grapple, demonstrating to a grateful world how vesical calculus, that incubus from which the stout heart of the Father of Medicine shrank dismayed, can be removed. *currente manu*, at a single sitting, quickly, safely, pleasantly; could they survey the Society as it is to-day, multiplied twenty-fold beyond their limit of expectation, endowed with instruments of research to them unknown, educated beyond their highest opportunity; and should they follow these brethren here present as they dispense throughout the whole length and breadth of the Commonwealth those kindly and skillful ministrations which give to the long-suffering sufferer solace and restoration, — could they view such a fruition, surpassing their utmost anticipations and fondest hopes, their hearts would overflow with exulting thankfulness.

A distinguished physician of Massachusetts once gave this toast: "Our country, however bounded, still our country; to be cherished with all our hearts and defended with all our arms."

So say we of our Massachusetts Medical Society. Its opinions and its methods may have changed somewhat from those of the time of Holyoke; we hope, we know, that another century will see modifications and improvements of our ideas of to-day; but the conservative principles of our association, its progressive aims, have been, are, and will remain the same. Changeless through every change, steadily augmenting its numbers and usefulness, our society, which for a hundred years has been the embodiment of medical knowledge and medical progress, well deserves in like manner to be cherished and defended.

A distinguished physician once gave this toast: "Our country, whether bounded by the Rio Grande, or how otherwise bounded, yet still our country." So say we of our Massachusetts Medical Society.

Our ideas have changed from those of Holyoke and his associates, and all of our opinions will be modified one hundred years hence; yet the principles of the society and its conservative opinions will ever remain the same, and steadily onward, both in principles and usefulness, may it ever advance, and as of old be cherished and defended.

Dr. White then introduced the Governor with the following words: —

The Commonwealth of Massachusetts and the Massachusetts Medical Society, — mutual servants and allies: the latter evinces its relations to the former by the care of her citizens and soldiers, in making our towns and habitations healthy; and her sanitary code we need not mention in the presence of her chief magistrate, one who appreciates all labors for humanity, and one whom we all especially honor, — GOVERNOR LONG.

To which the Governor responded as follows: —

I am sure that one of the most fundamental, though unwritten, laws of the Commonwealth is a sound mind and a sound body. One hundred years ago last October the people provided for the former by adopting the Constitution, by which the advancement of piety and progress were insured. About a year later she incorporated, over the signature of her first Governor, the Massachusetts Medical Society, and intrusted the lives and limbs of her makers to its careful keeping; and to-day we are celebrating not only her centennial, but also a century of progress onward, out of ignorance and doubt into the light of truth and learning.

Of all professions I suppose that that of medicine is most experimental and tentative. The law, the common law, has hardly taken a step forward for a century. The pulpit has only exemplified the "Sermon on the Mount," and that not always trustworthily. But without any personal knowledge from my end of the line — and I trust it will be many years before I have — I take it that medicine owes its splendid progress to its forgetting and discarding the ideas of yesterday, and therefore I speak of it, as of all professions the most experimental. However delightful the profession proves to the scientist, it is somewhat different, I fancy, to the patient, although its operations are done quickly, safely, and pleasantly.

Of all the sciences, then, medicine is the most liberal one; and while it gains so tremendously by such an organization as this, yet it should take care to avoid a danger which in the light of the present day is most obvious, and one which attends all such organizations, namely, limitation.

I bring to you to-day the good wishes of the Commonwealth. The State and society should go together; medicine and politics I am quite ready to admit go well together, only it is, perhaps, pleasanter to administer than to swallow the dose. This I may say, there is never any better or cleaner politician than the doctor. Both medicine and politics are unpleasant in the art of cure, and I wonder whether or not it is better to let nature have her way, and just as easy to recognize the best sentiments of her people and let them alone, only so far as to see that they have fair play, equal rights, and, particularly, good air, good water, and sufficient drainage within ten miles of Boston.

The chief significance of your professional body to the great body of the Commonwealth, which I represent here, the chief significance, I say, is not immediately in your scientific projects, nor so immediately in your researches, but in your relation to the homes of the Commonwealth.

In this relation, ministering to the relief of pain, in the sympathy of attendance, in the confidence and friendship of the family doctor, in the liberation of wife and child from sickness and death, — in all these you have the warmest gratitude and most powerful hold upon their affections.

The Commonwealth recognizes its dependence upon you. It also appreciates what a century of beneficent advantage it has been, and for which my lips can only pay a tribute of open admiration.

Finally, I can only say this: you are sometimes impatient with the Commonwealth's action in various ways, but in the long run the public sentiment of the Commonwealth vindicates itself. If, then, the State, through its law-makers, is not always ready to follow your counsel and do your bidding, yet believe me that its common sentiment is always with you in every generous step that you may take toward the saving of the body, and so far also of the soul.

The following sentiment was then given: —

"Harvard University: To her medicine in New England is indebted for a century of affectionate care; to her do we owe the demonstration of the fact that a system of medical education characterized by a definite course of studies and examinations based upon actual knowledge is not only wanted but demanded."

I call upon President Eliot, one to whom we are greatly indebted for such results.

PRESIDENT ELIOT responded: It always gives me great pleasure to come to the dinner of the Massachusetts Medical Society. If I had not been a college man I should probably have been a doctor. My great-grandfather was a minister who mostly practiced medicine. His diary mentions in the briefest possible manner his official duties: preached so and so on Sunday, November , text so and so; buried such a man on such a day, and christened a child on such a day; but when it came to tracing an epidemic through the dogs, pigs, and sheep of old York, Me., he expanded his diary into many pages, and showed that he was intended for a physician. Perhaps this is one of the reasons why I have taken an interest in the plans which the faculty of the Medical School have entertained toward its development. I have had occasion several times to come here and thank this society for the generous support it has always extended to Harvard and its branches, and to-day can only repeat the same old story. The subscriptions to the Medical School have reached 103,650, and we owe much of this to you in a very important sense. The community is willing to endow our medical universities because they are the birthplaces of medical men, and to this extent we owe it to you.

But allow me to say a few words upon another theme, for the interest of those who are looking forward with hope and expectation to the future. I believe that the profession of medicine is only just now for the first time in the history of civilization dimly discerning its future greatness. The professions of law and divinity have been highly organized for many centuries. Indeed, priesthoods have thus far proved the firmest and most durable of human institutions, and legal tribunals and guilds are not much inferior in permanence, although less universal. The medical profession, on the other hand, has only lately begun to organize itself effectively to exert a collective influence, and to take collective action through its schools, societies, and literature. Yet no profession has more to gain by collective action than that of medicine. The pupil of the isolated country doctor had but one master, few books, and very restricted clinical opportunities; the student at the modern medical school has forty masters, ample libraries, and an endless variety of bedside instruction. A few generations ago the knowledge and skill of the most sagacious and experienced physician were likely to perish with him, or to be precariously transmitted to a few immediate disciples. Now every accidental discovery, every result of long-continued observation, everything which medical sagacity discerns or genius divines, can be promulgated in societies, recorded in medical literature, and made easily accessible to future inquirers by catalogues and indices. Nothing which the fondest physician or surgeon learns need be lost to the profession or mankind. To heal the individual bodies brought under his care was almost the only aim of the good physician of preceding centuries; but now wider interests demand a share of his attention. He studies to prevent disease; he strives to root out of society the causes of physical degradation and contamination; he contends against noxious trades and injurious occupations; he fights contagion, and also the rational dread of it. In short, his mind ranges far beyond the healing of individuals to the welfare of the race. Now all these new and larger modes of action require cooperation, organization, and collective public influence; and many new arts had to be discovered and brought into use before this cooperation and organization be-

came possible. Without steam power, cheap printing, and rapid mails, the advances made in medicine by the last two generations could not have been achieved. It is a wonderful stride from the electuary of sowbugs, the nauseous salt extracted from men's skulls, and the king's magic touch, which Dr. Green told us about yesterday, to sulphate of morphia, ether, and quinine; but how short the time in which this progress has been accomplished! The life of this new country more than covers the period. It is not the advance of the physical and mental sciences alone which has made practicable the recent progress of medicine. The new art of bibliography is essential to modern medicine. The accumulating experience of civilized nations in constitutional government and in association for public objects has taught the medical profession how to organize itself and how to exert a useful public influence. The profession already begins to discharge a new and beneficent function through its influence upon sanitary and reformatory legislation; but not only is all such legislation actually very recent, but it has only lately become possible in modern states to have any such legislation or to get it enforced. In view of these things, I say that the century whose completion this society is celebrating to-day will hereafter be looked back upon as the birth-time of medicine as a learned and liberal profession. The calling of the priest or minister is ennobled by his conviction that he labors for the spiritual part of man, and that in a special sense he belongs to the army of the living God. The lawyer holds that the great interests of public justice and morality are promoted by his labors, and feels himself a member of a venerable and vigorous body. The educated physician ought henceforth to feel that his work underlies all other work for humanity, and that even his single, fleeting life enters into the corporate immortality of a beneficent and powerful organization.

Dr. White then introduced Judge Hoar with the following sentiment:—

"The relation of medicine to the State and legislation: may it become more intimate as civilization advances. We look to our eminent statesmen for their assistance in making it closer in many ways."

JUDGE HOAR replied: It gives me great pleasure to acknowledge the obligation. I was in some doubt as to what I could be indebted for the privilege of coming before you and participating in these your high solemnities, but upon thinking it over I first called to mind that ancient proverb, namely, "After forty every man is either a fool or a physician;" and being inclined to put the most charitable construction upon it, I find myself now among you. Another claim to being present at your celebration is that my earliest recollection dates back to my acquaintance with an ancient practitioner, a surgeon in the Revolution, and one of the earliest members of this society. The most valid reason of all for my being present, however, is that you might have that privilege that Burns thought so desirable, "to see yourselves as others see you," and after you had sung your own praises sufficiently to hear something about yourselves from a different point of view.

My earliest recollections of the medical profession are not at all favorable. They commence with an attack of the measles at the age of four, and on that occasion I delivered my mind to the doctor in regard to his manner of dealing, which led that worthy to observe

to my mother that "the boy must be out of his head." That experienced lady was satisfied that it was only a manifestation of my sincerity, to which I have adhered for the remainder of my days. I must say, however, that my respect for the medical profession has steadily increased from that day.

To adopt a Scriptural phrase, "and also as certain of your poets have said,"

"Little of all we value here
Wakes on the morn of its hundredth year
Without both feeling and looking queer,
In fact, there 's nothing that keeps its youth,
So far as I know, but a tree and truth."

[As the judge said this, he turned in acknowledgment to Dr. Holmes, who sat near him.] And with the health and vigor of a tree, and founded upon a scientific respect for truth, your society at this advanced age seems more likely to endure forever. A poet has said of a work of genius that it always finds us young and always keeps us so. Now I don't know but what the same compliment may be paid to the medical profession: you certainly always find us young, and I have no doubt to the best of your ability you always keep us so, or at least about "so so," if I may observe it, at any time of life.

The Massachusetts Medical Society has had one honor which I supposed his Excellency the Governor, in his pleasant address would have referred to: you have contributed to the service of the Commonwealth two of his distinguished predecessors, General Brooks and Governor Eustis.

I wish, however, gentlemen, from the point of view of a member of another profession, on this occasion to say seriously to you what I think has been the great service of this society to the public and the Commonwealth. In the first place, you have been the great barrier to this community against what Sir Thomas Brown so quaintly expresses as that class of "quacks and charlatans whose impostures are full of cruelty and worse than any other, and delude not only into pecuniary diversions, but the irreparable deceit of death." That is your first and highest claim to honor.

In the next place, I think that your society has done much to substitute the pride in an honorable profession for the personal rivalries and jealousies which were in early times the bane of all professions.

You have also steadily raised the standard of professional accomplishments and acquirements. To you we shall ever be indebted for what you have done in modifying the ancient medical practice; blood-letting is gone into the memories of things past, and you have shown a great inclination to substitute as your patron deity Apollo for Mercury, and to trust to the curative properties of sunshine rather than to calomel.

Finally, you have abolished the ancient pretense which was the curse of all professions. Miss Martineau says that "one of the most impressive things in her visit to this country was the terrible truthfulness of the Boston doctors."

You do not now rely upon what at any rate it would seem to many was much relied upon by your predecessors when they tried to seem wise, which Lord Bacon characterizes when he says that "when they know within themselves that they speak of that of which they do not well know would nevertheless seem to know of that of which they may not well speak."

Your medical profession, I think, has advanced to its present high and honorable position by its regard for sincerity and simplicity.

I cannot trust myself to give expression to my feeling of respect for you as a body of men, but when I think of you all as distributed over our Commonwealth in your individual relations to the people, trusted friends in time of sorrow and danger, giving strength to the weak and comfort to the despairing, the pillars of the State; each in your limited or widest sphere in all our towns and villages, I have no other purpose in rising than to call you blessed.

In conclusion I will simply say — and I always like to borrow from my friend the *doctor* when I can — that I wish for the continued and constant prosperity of this society, and

"May it live untroubled by woes and fears
For a second youth of a hundred years."

Dr. Holmes was thus happily introduced: —

History, that is nature, ever repeats herself, even in her highest types. We are assembled here below the presiding divinity of this hall (Apollo), who, as the father of Æsculapius, so appropriately overlooks our feasting. On rare occasions he revisits us, and, as the father of poets, is ever young, in whatever form he comes to-day, — Dr. Holmes.

DR. OLIVER WENDELL HOLMES was greeted with prolonged applause as he rose in response to Dr. White's introduction. By way of preface he mentioned the praise of the medical man which he was about to bestow, and said that though that praise was without reserve it was no more than was due, and from his own long retirement from practice not unfitting to come from his lips. He then read a characteristic poem, which is to be found in this number of the JOURNAL.

Next was introduced REV. PHILLIPS BROOKS. He spoke of the professions of theology and medicine as intrinsically and essentially associated. The society is like a great being which has lived through a century. How much suffering it has relieved in that time, and how it is to be congratulated for its labors and success! It receives the congratulations and the God-speed of the whole community as it starts off on the second century of its life. It is to be thanked not only for the care of the sick and the relief of suffering, but that it has laid its hands upon all classes, and has preserved the conditions upon which they do their work. So this great doctor who has lived comes and asks for support in the future as in the past. It is a great privilege that the doctor can study into the perpetual mystery of the human body. In the specialization of all human activity the medicine and ministry are temporarily separated, but the separation is only temporary, as is every separation of those who work in different fields of human life. In the battle with human sin, error, and suffering the combatants are temporarily separated, but as certainly as that sin and suffering are connected these combatants will be united again in the final attack of the good upon the evil. It is one of the advantages of occasions like this celebration that as the combatants march forward they may signal one another in a friendly way. [Applause.]

"Our distinguished guests from far and near," introduced DR. GROSS, who responded: —

MR. PRESIDENT — My task is a simple one, and as pleasant as it is simple, namely, to tender thanks in behalf of the guests of the Massachusetts Medical Society. I came here upon the kind invitation of your society extended through your distinguished chairman.

I did not intend to make a speech, but I found yesterday that your chairman was spotting me for some purpose, and I felt like a countryman who has fallen into the hands of a confidence man. At last he asked me to sit down with him for a moment, as he wished a word with me. I tried to back out, but to no purpose.

I stand in your presence to-day, among men who are old on the one hand and those who are young on the other. None of you are in your dotage, but some have jumped across the boundary line into a healthful infancy, and with the blessing of God may all your lives extend into good old age, and may you all meet at the end of the century.

I have heard a good deal about the Massachusetts Medical Society, but it never fell to my lot to meet it upon so interesting an occasion as this is. I come here to lay my respects at the feet of the association. I congratulate you upon the work which you have done and are to do hereafter. Young men of the Massachusetts Medical Society, do not forget the debt you owe to your predecessors, and do not forget that without their light, which has been showered upon you, you could but dimly discern your path, as if lighted with an oil lamp rather than by the electric light of the present day. It is too much the practice of young men to forget the work of their predecessors, and thus the light of science and duty. Yesterday, during the ceremonies at Cambridge, I could not help recalling what Harvard University has done in the education of the men of Massachusetts and of the whole American continent, and much of the interest which attaches to the Massachusetts Medical Society is due to the fact that many of its members are graduates of Harvard University. I cannot but remark the contributions of this association toward the support of Harvard University. It is a great school, and one which is still an example of progress,—an example which has not been adopted as yet, but it is sure to come about in the providence of God. Here in Massachusetts you have been blessed with the services of many distinguished men, but none of them more brilliant in any profession than the names of Ware, Hayward, Jackson, Bigelow, and Warren. I knew the elder Bigelow, an honored name, and if Massachusetts had never done anything more save to furnish to us that genius and his work on the *Limits of Nature in Disease* her name would be immortal.

As I look around me I fail to distinguish the form of Dr. J. B. S. Jackson. Death called him hence suddenly and unexpectedly. One of the last evenings of his life was spent in my parlor. I had a warm attachment for that man. With him I was greatly interested in the study of pathological anatomy. In my early life I came to Boston in 1839, with my manuscript of *Pathological Anatomy* under my arm, looking for a publisher, whom I had sought in vain in Philadelphia and New York; and Jackson was the first to speak a kind word for me, and then a sympathy grew up between us that ripened with age into a most intimate friendship.

Dr. White then said:—

While our profession is so earnestly engaged with the ills of mankind, and while we cannot pay much attention to the work of the past, we are fortunate in having them preserved for us.

I introduce Dr. George E. Ellis.

REV. DR. GEORGE E. ELLIS then spoke as follows:—

The Massachusetts Historical Society may well claim an interest in this centennial occasion. Its diligent and accomplished librarian, in his address to you, yesterday, gave you some idea of the contents of the ancient manuscripts and other sources from which he gathered his curious information. Having had the privilege of reading the whole of that address, of which only a fragment was spoken to you, I know what satisfaction you will find in its deliberate perusal. You will observe with professional approval one very striking fact, to which your attention is there drawn, namely, the purpose and effort from the very beginning of the legislature of Massachusetts to secure honor and dignity to the true medical profession by severe dealing with manifest quackery. The baffled attempt to obtain through our legislature, two years ago, the protection of our community from charlatans and incompetent practitioners was but the last of a long series of efforts in that direction, of which the first is found on our records in the very first year of this colony. And this is more noteworthy, as what is now represented as true medical science was then but in its infancy,—here and all over Christendom hardly distinguishable from empiricism. The acute old Puritan discernment could even then draw the line between the effrontery of a bold charlatan and the tentative purpose of a right-minded tyro in a critical calling. The historical society will show you, among its ancient portraits, one of the famous Dr. John Clark, perhaps the first here with a doctor's diploma from England, 1637-1664. He is said to have taken the lead in trepanning the skull. His portrait, venerable and sage, shows him with a skull on a table, boring into it with something that looks like a corkscrew.

It must have been to the equal satisfaction of members of both the professions when the clergy yielded up their ancient oversight of bodily maladies to the new generation of doctors of medicine. On many of the minister's diaries, and on some of the church records of our early years, are often found recipes for making ink, and for dealing with "the flux," sore throat, and other diseases. There is evidence that the old clerical treatment was Herculean,—as drastic as was their Calvinistic discipline for the soul. The stomach was the main place of assault. Heart and lungs were not of much consideration then, and the nerves do not appear to have been discovered as being such mischief workers as they are held to be now. We must remember, however, that it was a doctor of medicine, not of divinity, who, by pronouncing the first "afflicted" person in Salem, in 1692, to be "evidently under the evil hand of the devil," opened the direful tragedies of the witchcraft delusion. Experience has shown that it is better that the two professions should stand apart. I recall the case of a minister, ill-furnished and unsuccessful in that profession, who ventured, as he phrased it, to "take up doctoring." He was soon in the hands of the law, for malpractice. His explanation was that "in preaching most of what went into one ear went out of the other, while it was more risky to deal with the apothecary's stuff."

The wisdom of severing the professions is found in the fact that the worst and meanest of all the quacks among us are those who trifle with both professions and belong to neither. Ministers and physicians have at least one common object in dealing with the sub-

jects of their care. It is an advantage for a person under treatment, morally or physically, to know as clearly as possible what is the matter with him, — or, in our plain vernacular, "what ails him." It would be difficult to say which of the professions has the advantage in the diagnosis of disease, but their knowledge in each case exceeds their curative skill and power.

On the church records of the revered old Indian apostle and pastor at Roxbury, John Eliot, I find this entry, under date of 1632: "Mary Chase, the wife of William Chase, had a paralytic humor wh. fell into her backbone, so that she could not stir her body but as she was lifted, and filled her with great torture, & caused her back to goe out of joynt, & bunch out from ye beginning to the end; of wh. infirmity she lay 4 years & a half, & a great part of the time a sad spectacle of misery. But it pleased God to raise her again, & she bore children after it."

I have submitted this case professionally to Dr. Holmes. As your proclivities will lead you to prefer the doctor's account of it to the apostle's, I will read it to you as the close of my speech: —

296 BEACON STREET, June 3, 1881.

MY DEAR DR. ELLIS, — A consultation without seeing the patient is like a murder trial without the *corpus delicti* being in evidence. You remember the story of Mr. Jeremiah Mason and the witness who had had a vision in which the angel Gabriel informed him of some important facts: "Subpœna the angel Gabriel." So I should say, Carry us to the bedside of Mary Chase; but she has been under green bedclothes so long that I am afraid she would be hard to wake up.

We must guess as well as we can under the circumstances. The question is whether she had angular curvature, lateral curvature, or no curvature at all. If the first, angular curvature, you must consult such authorities as Bryant, Dewitt, and the rest. If you are not satisfied with these modern writers, all I have to say is, as I have said before, when asked whom to consult in such cases, Go to Pott, to Percival Pott, the famous surgeon of the last century, from whom this affection has received the name by which it is still well known of "Pott's disease;" for if a doctor has the luck to find out a new malady it is tied to his name like a tin kettle to a dog's tail, and he goes clattering down the highway of fame to posterity with his æolian attachment following at his heels.

As for lateral curvature, if that had existed, it seems as if the apostle Eliot would have said she bulged sideways, or something like that, instead of saying the backbone bunched out from beginning to end. Besides, I doubt if lateral curvature is apt to cause paralysis. Crooked backs are everywhere, as tailors and dressmakers know, and nobody expects to be palsied because one shoulder is higher than the other, — as Alexander the Great's was, and Alexander Pope's also.

I doubt whether Mary Chase had any real curvature at all. Her case looks to me like one of those *minoses*, as Marshall Hall called certain forms of hysteria which imitate different diseases, among the rest paralysis. The body of an hysterical patient will take on the look of all sorts of more serious affections. As for mental and moral manifestations, an hysterical girl will lie so that Sapphira would blush for her, and she could give lessons to a professional pickpocket in the art of stealing. Hysteria might well be described as possession, — possession by seven devils, except that this number is

quite insufficient to account for all the pranks played by the subjects of this extraordinary malady.

I do not want to say anything against Mary Chase, but I suspect that, getting nervous and tired and hysterical, she got into bed, which she found rather agreeable after too much housework, and perhaps too much going to meeting, liked it better and better, curled herself up into a bunch, which made her look as if her back was really distorted, found she was cosseted and posseted and prayed over and made much of, and so lay quiet until a false paralysis caught hold of her legs and held her there. If some one had "hollered" Fire! it is not unlikely that she would have jumped out of bed, as many other such paralytics have done under such circumstances. She could have moved, probably enough, if any one could have made her believe that she had the power of doing it. *Possumus quia posse videmur*. She had played *possum* so long that at last it became *non possum*. Yours very truly,

O. W. HOLMES, M. D.

PROF. ALEXANDER AGASSIZ was the last speaker. He said that the naturalists usually regarded themselves as offshoots of the medical profession. But biologists have not been seen to pay their debts to that profession. Physicians are looked upon by biologists as specialists who practice on the human race. Progress will be achieved as the whole animal kingdom is studied, not man alone. To the metaphysical doctor, not the doctor of metaphysics, must society look for progress in the future.

DR. WILLIAMS then rose, and said: —

We are not without links which connect us with the olden time. Another Warren is in the field, adding lustre to the name he bears. And a stately representative of the Fathers, who was among those present at a dinner given by this society to its first president on his hundredth birthday, but for the unfavorable weather would have graced our table with his presence. I ask the society to join me in offering our respects to him who has been during two whole generations of doctors *facile princeps*; an exemplar of honor, skill, and generous courtesy; a true Fellow of the Massachusetts Medical Society, — Edward Reynolds.

In closing DR. WHITE simply said: —

Thus ends our centennial anniversary, and may our children find our Society as prosperous a hundred years hence.

TRIPOLITH.

At a Berlin medical society meeting Professor von Langenbeck exhibited as a new material for forming plaster splints tripolith, which was originally used for stucco and decorative purposes, and has the advantage of lightness, and that when once dry it does not again easily absorb water. Tripolith, according to Dr. Wiehel, is an artificial mixture of gypsum, magnesium sulphate, and powdered cork. It hardens quicker than gypsum, and in the fresh condition is eight, while in the completely dried about twelve, per cent. lighter. — *Chemiker Zeitung*.

UNGUENT DIACHYLON.

Dr. A. Bauer states that Dr. Hebra had substituted vaseline for linseed oil in the composition of his celebrated ointment. — *Pharm. Zeitung*.

Medical and Surgical Journal.

THURSDAY, JUNE 23, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

NO. 4 PARK STREET, BOSTON, MASS.

THE MASSACHUSETTS MEDICAL SOCIETY'S HISTORICAL EXHIBITION.

IN the JOURNAL of last week the intention was expressed of returning to the consideration of the exhibition, which was one of the most marked features of the Massachusetts Centennial Celebration. The general tone of the centennial was, as was eminently fitting, strictly local. The exhibition was in tone and nature cosmopolitan, and when we speak of its universal character we are far from regretting the local flavor naturally attending the meeting; a peculiar zest was given to the enjoyment of the whole by the contrast between the cosmopolitan exhibit and the local celebration.

No part of the exhibit had more to do with this contrast than that of books and engravings. Beginning with the fifteenth century, many of the most important and most curious specimens of medical literature which the world has produced were collected and arranged in a manner calculated to furnish a graphic idea of the evolution of medical science. The marked feature of the exhibition, however, was the series of illustrated anatomies, many beautiful specimens of art from the domain of pathological anatomy and surgery being included. As a whole the exhibit gave an excellent idea of the rise and progress of anatomical illustration. Confining ourselves for a time to what we have called the principal line, we would draw attention at first to the anatomical works of the pre-Vesalian period.

The various editions of Mundinus, the graceful cuts of some of the earlier editions of Johann de Ketham, containing the earliest anatomical woodcuts, including Dr. Hunt's copy of the *editio princeps*, bearing date of 1494, the rude cuts of some of the German anatomists, may be all mustered, as far as anatomical work is concerned, under the leadership of Jacobus Berengarius Carpensis. Professor Holmes's copy of this work was one to satisfy the most exacting bibliophile.

It would be impossible to mention all the volumes that represented the next great stage of anatomical development. Beginning with Vesalius and Etienne — remarkable for his minimum of anatomy and maximum of non-essentials — and ending with Albinus, there was hardly an important anatomical work missing from the exhibit.

Vesalius would have rejoiced to have seen Grevin, Hammeo, Plater, Alberti, Bauhinn, and many others of the eighteenth-century anatomists shown in a position that rendered their indebtedness to himself

very evident, while Bedloo might have sympathized with him in seeing his gorgeous plates in the beautiful copy of Professor Holmes shown by the side of Couper's English edition of the same plates, published without acknowledgment of their source, — for book pirating is by no means an invention of the present day. Brown, on the other hand, would have fellowshiped with his countryman Couper, for his *Myographia* bore evidence of its lack of originality in the company in which it was shown; but to follow the anatomical plagiarisms would be altogether impossible in the space at our command.

A long series of works, among which we may mention an edition of Aselli with the rare colored woodcuts, the slightly known plates of Beretini, the *Osteographia* of Cheselden, an odd little specimen of the colored copper plates of Dagoty, the *Observationes Anatomicae* of Santorini, bring us to the epoch of Albinus, whose *Tabulae Scaletii et Musculorum* and the *Tabulae Ossium* in beautiful editions demonstrate his skill, taste, and learning. Haller and William Hunter were noticeable in the epoch that intervened between Albinus and Scarpa, Soemmering and Mascagni. Probably the brilliant-colored copy of the *Anatomia Universa* of Mascagni, loaned by Dr. J. C. Warren, was one of the most striking objects in the exhibition, but the beautiful engraving in Dr. Hunt's copy of Scarpa did not lose in effect, nor was the conscientiousness of Soemmering's production less perceptible in comparison with its gorgeous coloring.

Of the anatomists of our own century we can only say that, while many were shown, want of space prevented a full display of nineteenth-century work. The anatomical works were followed by a brilliant line of chromo-lithographic and other representations of pathological anatomy and surgery. Cruveilhier, Ricord, Mad. Boivin, Mad. Lachapelle, Bougery, Pirigoff, Hunter and Bell, Sibson and Cooper, formed a group not less interesting than the anatomists already mentioned. Then followed some very beautiful botanical plates; the grand works of Thornton, Hill, Blume, Miller, and many others giving rare representations of the application of pictorial art to scientific medicine.

We cannot even attempt to notice the hundreds of volumes of curiosia. There was the old *Ortus Sanitatis* and its long progeny of fifteenth and sixteenth century herbals, German and English; fifteenth-century tracts on Syphilis, the *Surgery of Taliacotins*, the works of Fallopius, Fabricius Hildanus, Fabricius ab Aquapendente, Pauc, Malpighius, Willis, Leuwenhoek, of Harvey the great and Gideon Harvey the little, of Bishop Berkeley, eloquent upon the virtue of Tar Water, and an original account of Perkins's Tractors. Not the least interesting in this department were the exceedingly rare and valuable original works on Cow-Pox, loaned by Dr. Henry A. Martin, whose name was also attached to many other rare pieces. Particularly noticeable, even among the many rare books, was Dr. Holmes's minute edition of Hippocrates, with notes by "Dr." Rabedais, published in 1545.

An especial object of interest in this celebration of

the nativity of the society, whose birth was so closely connected with the War of Independence, was the single volume of the unfinished *Anatomy of Vieq D'Azyr*, bearing the date of 1786. The pathetic story of his talented career, so early closed by too arduous devotion to the science of his choice, will always give additional interest to the magnificent folio which bears his name; but the present interest to which we especially refer lies in the dedication, of which we give a translation: "Louis XVI., to whom the thirteen States of the new world owe their liberty, the seas their independence, Europe peace, France its monuments of justice, benevolence, and humanity, science, letters, and arts a strong support, has deigned to accept the dedication of this work."

Of the engravings displayed it is only possible to say that they deserve quite as full a notice as the books.

The materia medica exhibit, divided into ten groups, arranged on each side of a passage on the right of the hall, attracted the attention of the visitor by its novel and picturesque appearance. The pressed medicinal plants from the Gray Herbarium at Cambridge papered the wall at one end of the hall, the botanical models from the College of Pharmacy covered a large table near the entrance, and hundreds of bottles from the cabinets of the College of Pharmacy and the Harvard Medical School were arranged along either side, interrupted only on the left by Mr. Sheppard's collection of Pharmacopœias and Dispensatories.

The principal groups were arranged in regular order, with numberless explanatory cards. They were, briefly, as follows:—

No. 1 contained upon its upper rows the vegetable and animal drugs which have been official during the entire century; that is, they were to be found in the Edinburgh Pharmacopœia of 1783, or the London Pharmacopœia of 1788, and in all the editions of that of the United States to the present time. The middle shelves of this group contained the chemicals, and the lower one the preparations which have stood the same test. These, the "Ancients and Honorables," were in full force, there being in the upper rows hardly a deficiency, excepting common articles not exhibited. Of the preparations, a complete catalogue was prepared for distribution, but only about fifty of the most interesting were shown. No. 2 contained those which have been discarded during the century. This group was naturally quite incomplete, still it contained a few things quaint and curious. No. 3, drugs and preparations introduced during the same time, was fully represented. No. 4, novelties not yet official. This interesting collection numbered from fifty to sixty specimens of crude drugs and a number of preparations; among the former, *coto quebracho*, *duboisia*, "*yerba santa*," and others attracted attention. Among these it was curious to see pepsin and "*cosmoline*," which have been used so long as to seem official. The elastic capsules, soft as India rubber, containing half an ounce each of cod-liver oil, were the most striking novelties of the season. These were in No. 5, devoted to modern specialties.

The case No. 6, containing proximate principles found in medicinal plants and animals, was unusually full and interesting, and included many of great rarity and value. The fixed oils, eighteen or twenty in number, included all of any interest to the physician. The volatile oils, fifty-four in number, represented almost every conceivable aromatic drug. Among those rarely seen were the oils (not oleoresins) of pepper, ginger, and cubeb, calamus, and East India sandal-wood. Menthol, vanillin, copaivic acid, as well as resorcin, were other interesting novelties. The centre of the case was filled with alkaloids and their salts. Of the alkaloids themselves and definite neutral or acid constituents there were one hundred and thirty-two. Among the rarer substances here were to be found crystallized aconitine, pseud- and jup-aconitine, pelletierine, cotoin, para- and hydro-cotoin, duboisine, curarine, crystallized tannic acid, pepsin (pure), and many non-commercial alkaloids of opium. Besides these there were salts of the commoner alkaloids in great variety, and a beautiful set of seventy alkaloids, acids, and salts from the cinchona. No. 7, miscellanies and curiosities, contained several obsolete medicinal fungi and numerous worthless things which have had a temporary place in therapeutics. No. 8, the Pharmacopœias and Dispensatories above mentioned, of all ages and languages, numbered over two hundred.

An annex to the Herbarium already mentioned was formed by living specimens of gualicum, hamatoxylon, cinchona, and other interesting plants of medicinal virtues upon the stage at the other end of the room.

The botanical models which attracted much attention were Anjou's complete set of thirty-seven flowers, fruits, etc., made upon a greatly enlarged scale (the peapod is about two feet long), and capable of being taken to pieces so as to display the internal structure. Of the specimens shown it is interesting to know that many were donations from leading manufacturers and dealers, or from druggists in the city, and that after the exhibition they were divided between the College of Pharmacy and the medical department of Harvard University, whose cabinets are thereby materially enriched.

We have already dwelt so long on the other portions that we have but space for a very brief mention of the surgical exhibit, which showed equal care in its preparation with the others already mentioned.

The observer was carried directly back over the hundred years by the two surgical cases of Jeffries and Warren, which were used on the opposing sides during the Revolution, but lay peacefully side by side in the hall. One of the most striking commentaries on the change in medical practice was the set of perhaps thirty lancets, the *vade mecum* of an old practitioner in the palmy days of phlebotomy. Waterhouse's lancets lay by the side of his silver snuff-box, in which vaccine lymph is reported to have been sent him by Jenner.

The gynecological instruments showed the development of the speculum and pessary into their present forms. One very old pessary, used by a practitioner

of Boston, too long "under green bedclothes" to take any lively interest in the matter, bore a striking resemblance to a pessary now largely sold under the name of a modern gynecologist.

A collection of old obstetrical instruments presented a marked contrast to the neighboring armamentarium of an obstetrician of to-day, and a stethoscope given by Laennec to Dr. Bowditch looked strangely rude by the side of the polished instruments of recent date.

Space fails for even the mention of the great variety of improved modern instruments loaned by the hospitals and instrument makers and surgeons of the city.

The gentlemen who were active in the establishment of this exhibition deserve well of their brethren. They helped show the connection of our profession on the one hand with literature and art, on the other with the natural sciences, while the surgical exhibit particularly showed the advances during the hundred years of the society's existence. We have purposely abstained from mentioning names; to catalogue those whose labor or contributions deserved notice would have been impossible, and to distinguish would have been invidious.

In conclusion we wish to say, if the exhibit had a fault it was one common to museums everywhere; the exhibit of so many treasures made it almost impossible to get the good that ought to be obtained from such collections. We hope to see such an exhibit repeated hereafter in a somewhat different or rather more limited form. Could the books be exhibited in some succeeding year, and sufficient time be taken for their arrangement, and a small catalogue issued which should contain such comments as would give a key for the benefit of undeveloped bibliophiles, it would afford a better opportunity for their due appreciation.

Such an exhibit might be followed in succeeding years by a similarly limited display of engravings, of surgical instruments, of drugs and pharmaceutical preparations, of splints and mechanical apparatus, and of hygienic appliances. In this way an entirely different and equally instructive display might be provided for a series of years.

Such exhibits would not be idle collections of curiosities, but would give instructive lessons in medical history, without some knowledge of which no one can properly appreciate the present condition of the profession. A knowledge of the past is the best guide for the future in medicine as well as in politics, and if this somewhat lengthy description shall have any influence in furthering such annual displays our columns will have been well employed.

THE BOYLSTON PRIZE AND THE MASSACHUSETTS MEDICAL SOCIETY PRIZE.

The Boylston medical committee announces, through its secretary, Dr. R. M. Hodges, among the advertisements on page 23 of this journal, the award of the Boylston Medical Prize for 1881. The successful contestant is Herbert W. Page, F. R. C. S., assistant surgeon of St. Mary's Hospital, London, for a disser-

tation on Injuries to the Back, without Apparent Mechanical Lesion, in their Surgical and Medico-Legal Aspects. No prize was awarded for any dissertation on the first subject proposed for 1881, The Effects of Drugs, during Lactation, on either Nurse or Nursing.

Both last year and this year the Boylston prize has gone to London, and has been carried off on both occasions by especially able and thorough essays. We must endeavor to console ourselves by the victories of Iroquois in England and of Foxhall in France, and at the same time borrow the closing lines of Punch's greeting to America upon the late success at the Derby:—

"Your health, Brother J.! Come and beat us again!
And cold grudge at a victory honestly scored
Melts away like the snow when the wine is outpoured."

The following are the questions proposed for 1882:—

I. Sewer Gas, so called (the Gas found in Sewers): What are its Physiological and Pathological Effects on Animals and Plants? An Experimental Inquiry.

The author of a dissertation on the above subject, considered worthy of a prize, will be entitled to a premium of three hundred dollars.

II. The Therapeutic Value of Food administered against or beyond the Patient's Appetite and Inclination.

The author of a dissertation on the above subject, considered worthy of a prize, will be entitled to a premium of two hundred dollars.

The following are the questions proposed for 1883:—

I. Measles, German Measles, and their Counterfeits.

II. The Differential Diagnosis of Abdominal Tumors, especially those connected with the Genito-Urinary Organs.

The author of a dissertation, considered worthy of a prize, on either of the subjects proposed for 1883 will be entitled to a premium of two hundred dollars.

It is proper to call attention to the fact that whereas for many years, and until within a few years, the capture of a Boylston Prize was considered a necessary step in the career of every ambitious Boston physician, the home competitors of late have been fewer and fewer, and we suspect we are correct in saying that this year not a single dissertation was sent in from Boston.

The same apathy is emphasized by the report of the committee for the award of the Massachusetts Medical Society Prize, which is derived from funds left to the society by the late Dr. Shattuck, and is open to members of the State Society only.

For this prize not a single dissertation was sent in this year, and of the few received last year none was found worthy of an award.

It is evident that the younger generation of medical men in this community either has no stomach for this kind of competition, or has found that it can put its talents where they will be more productive. We suspect that the rapid changes in modern medical science

and the extent of modern medical periodical literature have each a part in the production of this apparent listlessness, which we none the less regret to record.

MEDICAL NOTES.

—The annual meeting of the National Board of Health was held in Washington, D. C., June 1st and 2d. The board reelected its former officers.

—We learn from the *Wiener Medizinische Wochenschrift*, No. 22, that Professor Billroth's patient, on whom he performed excision of the pylorus for cancer on January 29th, has just died in Vienna. The case, surgically speaking, has become historical, for the operation was quite a new departure, and one which, but a short time ago, would have been considered impracticable. The case is rendered more interesting by the fact that an autopsy was obtained, and that thus the conditions of parts post mortem has been accurately studied. Dr. Zemann—in the absence of Heschl, the director of the Pathological Institute, whose death from the effects of a post-mortem wound has since occurred—conducted the examination. He found that death had resulted from metastatic deposits of cancer throughout the entire peritoneum, the duodenum and jejunum being likewise coated with a similar deposit, so that it was impossible to separate them one from another. As regards the stomach, it is stated that it retained its natural form, and that no one unacquainted with the operation to which it had been subjected would have observed anything remarkable about it, or guessed that fourteen centimetres had been removed from it. The duodenum had been attached to its lesser curvature, so that a little pouching was observable along the greater curvature. The woman had not suffered from any digestive troubles, but had taken and retained her food very well. At the point of junction there was no stenosis, the thumb being easily passed through the orifice. The union was perfect in all respects, so that hardly any scar could be perceived along the line of the suture.—*Medical Times and Gazette*.

NEW YORK.

—The last meeting of the Academy of Medicine for the present season was held on June 16th, when Dr. A. B. Judson read a paper on the use of crutches in the treatment of joint diseases of the lower extremity. On the same evening Dr. Hammond gave a reception at his residence in honor of the American Neurological Association, which was then in session in the city.

—Two cases of death from hydrophobia have recently been reported, one of them occurring in West Forty-Third Street, and one in Bellevue Hospital. The patients were lads of eleven and thirteen, respectively, and in each instance were bitten about the face by dogs some two months before the development of hydrophobic symptoms.

—The twenty-second annual commencement of the Long Island College Hospital was held at the Brook-

lyn Academy of Music on the 14th of June, when Charles J. Thomas, of Ohio, was the valedictorian, and the Rev. Henry Ward Beecher delivered the address to the graduating class, which numbered fifty-one members. The one-hundred-dollar prize was awarded to the essay of Dr. Albert J. Leffingwell.

—Dr. Rose, veterinary surgeon for Richmond County, Staten Island, claims to have discovered in the lungs of a cow which died of pleuro-pneumonia the ovum of an insect which he believes to be the destructive agent in that disease among cattle. The matter is to be brought before the New York College of Veterinary Surgeons for thorough investigation.

—The health officer of the port, Dr. Wm. H. Smith, has recently caused to be issued two official communications—one to the owners and agents of steamship passenger lines, and one to the health authorities of the interior of New York and of the Western States—in reference to the danger of the spread of infection by the vast numbers of emigrants now arriving in this country. In the first he showed that small-pox had been unprecedentedly frequent on board the passenger steamers arriving during the past few months, and pointed out that the incubation period of the disease—fourteen days—was so much longer than the average passage of steamships from many of the European ports to New York that there was great danger of the disease developing far in the interior of the country. As it was apparent, he continued, that no amount of vigilance at the port of New York could prevent this result, since the infected emigrant might pass quarantine perfectly well, it was of importance that every available means should be employed in these foreign ports to prevent the infection of emigrants and arrest the propagation of the disease. A careful inspection by competent medical officers of every emigrant and the vaccination of all unprotected persons would do much to accomplish this object; and in the absence of either power or inclination on the part of the constituted authorities to do this, it was exceedingly desirable that the owners and agents of steamship lines should take it into their own hands to inspect, direct, and control the movements of emigrant passengers from the time of their arrival at the port until their departure. He then went on to say that the condition and management of too many of the passenger steamers, as regards the proper care of infectious and contagious diseases, were objectionable and reprehensible. Hospital accommodations, if such they might be called, were in some instances provided in the midst of the crowded steerage, where neither sufficient light nor air nor proper isolation could be secured. When vessels arrived in port with small-pox on board it was necessary to remove the whole number of well steerage passengers to an isolated island for observation during the usual incubation period of the disease; and notwithstanding the serious inconvenience to all and the great expense to the owners, it could not be doubted that this alternative was far better than the admission of a cargo of infected emigrants to the dense population of our cities and the crowded thoroughfares of the interior. Better than

either, Dr. Smith pointed out, would be such watchfulness and vigilance on the part of medical officers as would secure early and complete isolation of the sick in hospital rooms that would afford sufficient ventilation and comfort to the sick, and opportunity for the complete seclusion of real or suspected cases of contagious disease. Such violations of hygiene and common sense as had too commonly been the rule on these vessels, he, announced in conclusion, would in the future be likely to subject to a quarantine of observation all passengers who might be so unfortunate as to have taken passage on steamships having small-pox on board, with such hospital accommodations as had been described.

In the second communication referred to, Dr. Smith states that experience and earnest consideration of the subject during the past year have confirmed the opinion that a careful inspection of all emigrants at certain points west of the maritime quarantines is essential for the protection of the country from the introduction of this form of contagious disease. In the absence of such action on the part of the municipal or state authorities, the National Board of Health, it was believed, had authority, under its reserved powers for the regulation of interstate quarantines, to secure the desired inspection of emigrants at such distributing centres as might be necessary for the protection of adjacent States. At intermediate localities the authorities, it was hoped, would establish a careful inspection, and, for a short period, maintain a close supervision of all emigrants who arrived to remain for any considerable time. If this management was practiced by the health authorities along the great thoroughfares westward of the Atlantic seaboard it was confidently believed that the introduction of contagious disease through infected emigrants would be effectually prevented.

CHICAGO.

— The faculty of Rush College at a recent meeting elected Dr. J. Suydam Knox to the position of adjunct professor of diseases of children. This is a new position in the college.

— In addition to the laws regulating the practice of dentistry and pharmacy passed by the last legislature, an act was passed that may become very vital to the health of Chicago. It is a law requiring an inspection and approval by the commissioner of health of the plans and specifications of every house proposed to be built, in respect to the ventilation, sewerage, and plumbing. If he fails to approve any plans submitted to him, and on the ground of lack of sanitary care and precautions, it will amount to a prohibition of the progress of the building. Plumbers are required also, after they have completed their work for any house, to notify the health department that such work is ready for inspection, and they are prohibited from covering it up till it is inspected and approved. So, if the law is executed fearlessly by the health department, as there can be no doubt it will be, the commissioner has it in his power to establish to a certainty the sanitary conditions, in the particulars mentioned, of every house hereafter built in the city.

Doubtless there will be some difficulty in carrying out the provisions of the law until more funds are appropriated by the common council for the pay of the additional inspectors that will be required. But there is little question the council will grant the means necessary, as the municipality cannot afford to forego the advantages and benefits likely to accrue from such a law.

— Anent the health department it is worthy of record that Mayor Harrison has commenced his second term, to which he was elected a few weeks ago, by reappointing Dr. DeWolfe as health commissioner. The city administration is democratic; the commissioner is a republican, and was appointed nearly four years ago by a republican administration. He has held the office continuously since, and is now reappointed on the basis of a fair and clean record of the efficient administration of his office.

— Dr. Daniel T. Nelson, for many years professor of physiology in the Chicago Medical College, has been appointed adjunct professor of gynecology in Rush College.

Miscellany.

THE TITLE OF ESQUIRE.

MR. EDITOR, — Dr. Green, in his interesting Centennial Address before the Massachusetts Medical Society, says, "The records follow the precedent of the act in withholding the medical title from Dr. Holyoke's name. Perhaps it was because Dr. Holyoke held a commission as justice of the peace, and the title of esquire at that time carried a great deal of dignity with it." Dr. Holyoke's medical title does not appear in the *act* because all the medical petitioners failed to add their titles to their signatures, and there was nothing to distinguish them from laymen. This loose fashion was almost as common then as now (even in medical communications), and often leads to confusion. The medical degree should *always* be appended to the signature, except in private communications. Under the common law every physician is (in common with barristers and sergeants at law) entitled to the title of *Esquire*, and the *proper* mode of address to a physician (say Dr. Holyoke) would be Edward Augustus Holyoke, *Esquire*, M. D. Surgeons (even without a degree) are also (in common with attorneys or counselors at law, justices of the peace, army and naval officers, and all persons holding a *government* commission) entitled to be addressed as *Esquire*. Blackstone says (vol. i. p. 404), "Before esquires the heralds rank colonels, sergeants at law, and doctors in the learned professions." In the time of Elizabeth "doctors in physic and sergeants at law had precedence of both knights and baronets." Vide *Nobilitas*, p. 116. At present doctors of the *universities* rank "with knights and above queen's counsel, deans, masters in chancery, chancellors, admirals, generals, barristers, and esquires." Vide *Precedence*, N. and Q., 4 S., xii. p. 282. General Grant's degree as LL. D. places him in the order of precedence on a par with a knight, and above deans, queen's counsel, generals, and others before mentioned. "The wives of doctors rank among women as their husbands among men, and the daughters of doctors rank with the daughters of knights." ORDER.

REPORTED MORTALITY FOR THE WEEK ENDING JUNE 11, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2362 (no reports from New Orleans or Buffalo); 938 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 635, consumption 371, lung diseases 173, diphtheria 163, diarrhoeal diseases 129, scarlet fever 87, cerebro-spinal meningitis 61, small-pox 52, measles 36, typhoid fever 35, malarial fever 24, whooping-cough 17, erysipelas 13, puerperal fever 12, typhus fever six, malignant pustule one. In addition, Nashville two deaths from diarrhoeal diseases, two from consumption, one each from typhoid fever, puerperal fever, and lung diseases: total deaths and deaths under five years not given. From *cerebro-spinal meningitis*, New York 13, Chicago 11, Pittsburgh nine, St. Louis seven, Milwaukee six, Baltimore and New Haven three, Philadelphia and Cincinnati two, Charleston, Cambridge, Holyoke, Haverhill, and Webster one. From *small-pox*, Philadelphia 29, New York 15, Chicago four, Brooklyn two, Baltimore and Pittsburgh one. From *measles*, New York 24, Providence three, Brooklyn, Baltimore, and Cincinnati two, Philadelphia, Milwaukee, and Woburn one. From *typhoid fever*, Philadelphia six, New York, Chicago, Cincinnati, and Charleston four, Providence three, St. Louis, Baltimore, and Pittsburgh two, Brooklyn, Boston, District of Columbia, and Milwaukee one. From *malarial fevers*, New York eight, St. Louis four, District of Columbia three, Milwaukee and Charleston two, Philadelphia, Brooklyn, Chicago, Baltimore, and New Haven one. From *whooping-cough*, Chicago four, New York, Brooklyn, and Baltimore two, Philadelphia, St. Louis, Cincinnati, District of Columbia, Pittsburgh, Providence, and Milford one. From *erysipelas*, Baltimore two, New York, Philadelphia, Brooklyn, St. Louis, Pittsburgh, Milwaukee, New Haven, Fall River, Lynn, Northampton, and Webster one. From *puerperal fever*, Boston four, New York and St. Louis two, Cincinnati, District of Columbia, Milwaukee, and Quincy one. From *typhus fever*, New York five, Philadelphia one. From *malignant pustule*, Springfield one.

Twenty cases of small-pox were reported in Brooklyn, 18 in

Chicago, two in Boston, one in Baltimore, 12 in Pittsburgh, one in New Haven; diphtheria 19, scarlet fever 11, in Boston; diphtheria nine, scarlet fever nine, in Milwaukee.

In 39 cities and towns of Massachusetts, with a population of 1,025,090 (population of the State 1,783,086), the total death rate for the week was 17.75, against 17.62 and 17.13 for the previous two weeks.

For the week ending May 21st in 149 German cities and towns, with an estimated population of 7,837,787, the death-rate was 26.3. Deaths reported 3968; under five 1806: pulmonary consumption 587, acute diseases of the respiratory organs 399, diarrhoeal diseases 178, diphtheria and croup 115, scarlet fever 73, whooping-cough 52, typhoid fever 43, measles and *rötheln* 28, puerperal fever 23, typhus fever (Königsberg seven, Danzig, Elling, Thorn, Tilsit, Erfurt two, Berlin two) 15, small-pox (Königsberg, Berlin two, Aachen three) six. The death-rates ranged from 15.7 in Metz to 41.7 in Ansburg; Königsberg 34.3; Breslau 35.7; Munich 39.1; Dresden 26.2; Leipzig 18.9; Hamburg 25.4; Hanover 18.6; Bremen 29.7; Cologne 26.2; Frankfurt 24.3; Strasburg 32.8.

For the week ending May 28th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 20. Deaths reported 2912: acute diseases of the respiratory organs (London) 241, measles 125, small-pox (London 92) 94, whooping-cough 84, scarlet fever 68, fever 42, diarrhoea 27, diphtheria 12. The death-rates ranged from 13.9 in Plymouth to 24.2 in Liverpool; Birmingham 15.7; Bristol 17.1; London 19.8; Leeds 20.7; Manchester 22.3; Sheffield 22.5. In Edinburgh 19.4; Glasgow 19.1; Dublin 24.9.

In the 21 chief towns in Switzerland, for the week ending May 28th, population 479,934, there were 32 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 11, measles nine, diphtheria and croup six, small-pox two, puerperal fever two, scarlet fever one. The death-rates were: Geneva 14.4; Zurich 29.1; Basle 25.1; Berne 23.4; St. Imier 21.7.

The meteorological record for the week in Boston was as follows:—

H. LENOX HODGE, M. D.

ON June 10th, at his home in Philadelphia, Dr. H. Lenox Hodge died, in the forty-fifth year of his age, of heart disease, with embolic pneumonia and thrombosis of all the extremities. Dr. Hodge was the son of Prof. Hugh L. Hodge, and was graduated at the University of Pennsylvania in 1858. In 1861 he was appointed demonstrator of anatomy at his Alma Mater, which position he occupied at the time of his death. He also delivered independent courses of lectures to private students upon operative surgery. Having served as resident physician in the Pennsylvania Hospital, when the Presbyterian Hospital was opened in 1872 he became attending surgeon to that institution, and for several years he has been surgeon to the Children's Hospital. He also served in the Satterlee Hospital in West Philadelphia during the war, belonging to the Pennsylvania Reserve Corps of Surgeons. He accompanied the Army of the Potomac at the time of the advance upon Richmond, and was also present at the battle of Gettysburg.

Dr. Hodge was a member of the American Medical Association, Philadelphia County Medical, Obstetrical, and Pathological Societies (of the latter he was ex-president), and a Fellow of the College of Physicians. He was not a voluminous writer, but his medical contributions were of a high order. In his professional career he was very successful, and enjoyed a large practice, moving in the best social circles. Personally he was universally liked by all who came in contact with him for his uniform courtesy of demeanor, his great kindness of heart, and his unassuming Christian character. A young son and a wide circle of friends sincerely mourn his loss. "He was a man, take him for all in all, we never shall see his like again." F. W.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JUNE 11, 1881, TO JUNE 17, 1881.

HARISLEE, A., major and surgeon. To proceed to the cantonment on the Uncompaggre, Colo., and report for duty to Colonel Mackenzie, 4th Cavalry, commanding. S. O., 113, Department of the Missouri, June 8, 1881.

HARVARD MEDICAL SCHOOL. — The Class Association of the Class of 1878 has obtained room 55, Fayer Hall, at the University, for the local part of the cross-commencement day, Wednesday, June 29, 1881. A punch will be served, *treats at the classes omitted*. The third annual dinner of the Class of 1878 will be given at the Hotel Vendome, on Wednesday evening, at half past six o'clock. This is the first time that the Medical School has been represented at Harvard University, the commencement exercises by any class association, and the Class of 1878 is the only class that has succeeded in sending its members together after their graduation.

VERMONT MEDICAL SOCIETY. — The semi-annual meeting of the society will be held in the city of Vergennes on Friday and Saturday, June 24th and 25th, commencing about noon on Friday. The morning of the evening and a part of the following day. The valedictory address will be delivered

on Friday evening. Many interesting papers on medical topics are expected. The resident members of the society propose some pleasant entertainment during the sessions. Important business is to come before the society. The railroads will extend the usual courtesy of fare one way to all who attend, and the hotels will furnish free carriages to and from the depot.

APPOINTMENTS. — The following appointments have been recently made: —

Visiting physician to City Hospital, Dr. Allan Sumner.
Physicians to out-patients, City Hospital, Dr. T. M. Rotch, Dr. Edward J. Forster.
Surgeon to out-patients, City Hospital, Dr. M. H. Richardson.
Surgeon to out-patients, Massachusetts General Hospital, Dr. Arthur T. Cabot.

CORRECTION. — In the report of the Massachusetts Medical Society in the last number, page 568, it should have been stated that the motion to adjourn to the day previous to the next annual meeting was carried.

ERRATA. — In the last number of the JOURNAL, page 567, first column, lines 45 and 46, for Heywood read Hayward; second column, line 24, for Cann read Conn.

MEDICAL SOCIETIES: THEIR ORGANIZATION AND THE NATURE OF THEIR WORK.¹

BY J. COLLINS WARREN, M. D.

IN Wisconsin the society was almost destroyed by being "a delegated body," through the neglect in organizing local societies, and of those organized to send delegates. The Wisconsin society now consists of permanent members entirely; for although delegates are admitted, these prefer to become permanent members. Such facts as these justify the action of those who refused to permit similar changes in the organization of our society.²

Under the present organization in Illinois, effected in 1878, there are still delegates, who represent local societies, medical colleges, hospitals, lunatic asylums, and other permanently organized institutions in the State.³ After serving one year in this capacity, they become permanent members. There is a judicial council of nine members, whose term of office is three years. Its duty is to decide all questions of an ethical and judicial character.

The manner of dealing with public hygiene and medical license is in striking contrast to that of those States previously mentioned, the work being done independently of the society, although the latter has exerted itself to bring about legislation upon these matters.

The Illinois Medical Society appointed a committee to memorialize the Legislature to establish a board of health in 1876. The committee met with great opposition. They were assisted by a committee of the American Medical Association through Dr. Johnson, their chairman, and also by the profession of Chicago. The board has been partially successful in collecting vital statistics. Dr. Ranch, the secretary, states in the report for 1880 that the board has no power to enforce this portion of the law, which devolves upon the county clerks, who frequently claim exemption from the discharge of that duty, proper compensation and assistance not being afforded by the county supervisors. In this report he urges that a committee be appointed on the law regulating the practice of medicine, and another on vital statistics, both of whom to coöperate with the state board in securing sufficient enforcement of the laws. At the last meeting of the society in 1880, it was proposed to memorialize the Legislature to secure the enactment of a law to create a school board of health for each county, consisting of the superintendent of schools, the surveyor, and one physician, the duties of the board being to inspect all sites and plans for schools and their sanitary condition.

The time of the Board of Health has been chiefly taken up in carrying on a work which in no other State has been assigned to such a body, namely, the execution of the law to regulate the practice of medicine.⁴ The act was passed in 1877. In organizing the board the governor appointed three "regular" physicians, one homœopath, one eclectic, and two

members at large. All physicians who had not been in practice ten years were required to show their diplomas to the board, that body reserving to itself the right to decide whether the school granting the diploma came up to a proper standard. If the candidate had no diploma he was required to pass an examination. These examinations have been largely "written," and a perusal of the papers show them to be of a high standard. The fines for violation of the act vary from fifty to five hundred dollars. Quite a variety of classes of individuals were found undertaking to practice. Among these it is important to note, in view of certain similar tendencies in this State, that there were a number of colleges whose curriculum was too short, and the work of teaching too carelessly done, and others who did no teaching at all, although chartered schools, their function being the sale of diplomas. There were many holding diplomas that did not belong to them. Forty-one practitioners were found under assumed names. The board went actively to work: held meetings in different parts of the State, and in the first year issued over five thousand certificates. It was thought that the difficulties in the way of determining the status of the thousands of practitioners scattered all over the State would be insurmountable, but the examining body being also the State Board of Health, the provisions of the law requiring the registration of practitioners as a part of the machinery necessary for securing the vital statistics of the State became an efficient means of overcoming this difficulty. Dr. Johnson is of the opinion that for this reason mainly the regulation of the practice of medicine can best be attended to by state boards of health. He believes that the law should compel every practitioner to pass an examination, as it has been found practically very difficult to discriminate between diplomas from the various colleges.⁵

There is published an annual "Illinois State Medical Register."

At the last meeting, Dr. N. S. Davis, the permanent secretary, who for thirty years had served the society in different capacities, sent in his resignation, which was received and accepted with much regret.

Glancing at other States, it may be noted that in Arkansas futile efforts have been made to secure an insane asylum, a board of health, the registration of vital statistics, and a law to regulate the practice of medicine. An excellent plan in Indiana is the appointment of a committee of three on State legislation in each county. The State society has issued to members of the Legislature copies of articles published in its Transactions, on State medicine. Louisiana has been active in urging upon the Legislature the needs of State medicine. It has been said that no State in the Union was better protected against impositions of all kinds. A law to regulate the practice of medicine was enacted in 1808, and amended in 1816, 1817, and 1840. The various provisions were repealed in 1852, without encountering the opposition of any: "for such was the

⁵ The number of unqualified practitioners has been diminished by 1750 since the law went into operation. It is estimated that about 550 of those now practicing and qualified were compelled through the law. The board has found that the clause which exempts physicians who had practiced in the State for ten years prior to July 1, 1877, "has rendered its duties more arduous and delicate than they would otherwise have been." Nearly one half of the spurious diplomas came from Philadelphia, and the greater part of the remainder from Cincinnati and St. Louis. The "schools" recognized by the board were the regular, eclectic, homœopathic, and physio-medical. (Second Annual Report of the State Board of Health of Illinois. Springfield. 1881.)

¹ Concluded from page 585.

³ One delegate is elected for every five members of the local societies. Each faculty is entitled to two delegates, and each hospital to one delegate. The annual assessment is five dollars.

⁴ Dr. H. O. Johnson. Transactions of the American Medical Association, vol. xxx.

execution of these laws that the State was infested with quacks and patent medicines, and whilst the laws imposed taxes and other burdens on the good, their penalties against the bad could not be enforced."¹ In Mississippi laws to regulate the practice of medicine are deemed premature until better appreciated by the people. The New York license law requires every practitioner to register, showing a suitable diploma. The penalty is a fine, varying from fifty to two hundred dollars. This has the advantage of avoiding a mixed board, and does not oblige physicians to indorse any "sect."

Having thus passed in review a number of associations of medical men, which, although in some cases formed for widely different purposes from our own, present peculiarities of interest to our Fellows, let us pause to consider whether we can gather from the experience of others hints which will be of use to us in carrying on our future work.

With the organization of our society we have certainly reason to be content. One of its greatest merits is its simplicity; there is no complicated system of delegates, "permanent" or "associate" members. By it the whole regular profession of the State is united into one compact body, which, through its council meeting at stated intervals, is able to do a large amount of work with a minimum of friction. The tables of Toner and Chaill² show in no State such figures as are credited to Massachusetts, which stands alone in wealth and numbers. Nowhere have I been able to find machinery which could do the work for which our society is designed in so satisfactory a manner. Under these circumstances we ought to be able to accomplish a great deal of good for the community in which we live. Let us glance, therefore, at some of the questions of the day which interest us as medical men.

Most prominent among these is the great question of public health or preventive medicine, the history of which dates back nearly one half a century to what may be called the period of its birth in modern times. It was after the cholera epidemic of 1830 that attention was first drawn to this question in Europe, and it is since that time that it has risen to the rank of one of the departments of science. The great work which has been accomplished in England also during this period has been of almost incalculable benefit to the civilized world. It is only, however, during the last decade that this vital question has actively engaged the attention of medical men in the United States. The first State Board of Health in this country was formed in Massachusetts in 1869, and to-day we have, besides the National Board of Health, similar boards in twenty-three of the States,³ in addition to numerous local organizations throughout the cities and counties of the country. Our recent pestilences have greatly stimulated this movement, which even with its present crude machinery has, on more than one occasion, demonstrated that sanitary science has not only been able to save life, but, what perhaps appeals more forcibly still to the American legislator's mind, has been

productive of results involving substantial pecuniary benefits.

There still remains much to be done, and doubtless many disappointments to be endured, before we reach the desired stage of perfection in this to the nation most vital department of science. When the General Board of Health came into existence in England it was so far in advance of public opinion that it soon fell to the ground, and a similar fate befell the splendid sanitary organization which was built up out of its ruins.⁴ The record of many States is far from encouraging. In Indiana there is still no board of health, but there are laws to protect animals from Texas cattle disease, fish from poisoning, and hogs from hog cholera. In Maine, where the State society has striven hard but unsuccessfully to obtain a board, there has been an annual appropriation of four thousand dollars for bounty on wolves, to protect sheep. When this argument was brought forward as a reason for asking an appropriation for the protection of man, the bounty was withdrawn. Unfortunately Massachusetts is not in a position to smile at the lack of appreciation of these important questions by her sister States. It has been said that our own State Board, which in its original form served as a model for the whole Union, has been worse than abolished.⁵ Its efficiency has, in the opinion of medical men, been seriously impaired by the cumbrous machinery of which it now forms a part. The City Board of Health is in danger, and at a time, too, when we are threatened with a serious epidemic. It behooves our society, as an association of men who are better qualified to judge of the importance of these matters than any others in the State, to make its influence felt both by active interference through the agency of committees and by the dissemination of sound views on questions relating to the health of the community; and this, it seems to me, is one of the directions in which we are able to increase our sphere of usefulness. From time to time it has been customary to appoint committees for the purpose of memorializing the Legislature to protect the interests of the profession, or to offer testimony for or against certain questions brought before that body. This has been done, however, in a somewhat desultory manner, and it is more frequently the result of individual enterprise that the "hearings" at the State House receive the benefit of sound medical testimony. The British Medical Association intrusts this work to the Parliamentary Bills' Committee, and it would seem eminently desirable that it should be placed in the hands of a permanent committee, who with time and experience would become a trained body of men, qualified to represent the society on all such occasions, and to give a well-digested opinion on all medical subjects. As very crude notions are held by representatives of the people in this State, not only of the practice of medicine but of State medicine, these questions should on every occasion have the benefit of all the light which the best talent of a powerful society is able to shed upon them. It would hardly be advisable to imitate the Alabama plan, and endeavor to obtain complete control of a work portions of which are not within the physician's sphere.

One of the questions of the day which is beginning to attract the general attention of physicians, and on

⁵ In 1880 the Board of Health was united with the Boards of Lunacy and Charity.

which an opinion will probably before long be expected from the society, is the regulation of the practice of medicine by means of legislative enactments.

The exaction of a requisite amount of medical skill by law is, as we all know, a measure which is of more vital importance to the public than to the medical profession; for experience has shown that the money which goes into the pocket of the charlatan would rarely, in his absence, be diverted into respectable medical channels. The suffering caused by the ignorant practitioner is, on the other hand, borne by the laity who patronize him. We should therefore let the public clearly understand that it is they we are seeking to protect, and not ourselves, in case we advise legal remedies for the evil. That the evil exists, and that it exists in a very aggravated form in this State, is, I think, denied by no one.

It was for the purpose of checking these irregularities that our society was originally founded, that the public might be able to discriminate between the honest and the wicked and ignorant.¹ Until the year 1840, nearly every State afforded some protection of this sort, but with the period of development of the so-called "sects" of medicine it has become inoperative or obsolete, or has been repealed. Connecticut had a law, dating back to 1792, empowering the State society to regulate the standard requisite for a practitioner. But in 1848 the same authority was given to the Botanic-Medical Society, in 1855 to the eclectics, and in 1864 to the homœopaths.² Maryland also had a law authorizing the State society to examine and license, which was practically amended by a law in favor of Thomsonians. New York has had an almost identical experience, as also this State. The State societies after this period were obliged to content themselves with maintaining a high standard among their own members, thus making it always possible for the public to obtain the services of a well-educated practitioner.

All restraints having thus been removed, the more flagrant forms of quackery began to thrive, until the credulity of the public has been abused to an extent probably unparalleled in modern times. The enterprise to which unrestrained license has given rise has led even to extensive criminal practices, which it is acknowledged the common law is powerless to prevent. Many States have therefore found it necessary to enact laws to regulate a system which is so productive of evil, and such laws are now in force not only in those States already mentioned, but also in California, Kentucky, New Hampshire, Vermont, and Pennsylvania, many of which were framed in imitation of the Canadian laws, the most noteworthy feature of which is the provision giving a position to the homœopaths and eclectics on the board of examiners.³

¹ See page 553.

² A "mixed" commission, consisting of one homœopath, one eclectic, and one regular physician, has recently been appointed to draft a medical practice act.

³ The following is a summary of the law proposed by a committee of the American Social Science Association and presented to the Legislature of this State in 1880, as summarized in an article in the *International Review* for April, 1881, by Dr. Ernest W. Cushing, who gives an able sketch of legislation on this question:—

"There should be one examining board, comprising representatives of the three medical societies,—under favorable circumstances, of dentistry and pharmacy also. All candidates for license ought to be examined directly by the board. The subject of therapeutics might be totally omitted from such examinations for the sake of harmony; or, as in Illinois, persons holding 'special or peculiar views' might be allowed, on request, to appear before individual members of the board for examination on such subjects. If diplomas must be received as evidence of qualification for licenses, the

From the examples already given some estimate may be made of the effectiveness of these laws. Their advocates do not pretend that they are without defects. They have been chiefly successful in driving peripatetic practitioners out of the State, in checking the sale of bogus diplomas, and in making the struggle for existence of the more notorious form of quackery uncertain and difficult.

On the other hand, these laws are not without grave defects. They have been chiefly objected to as partaking of the character of class legislation, and it is difficult to persuade our legislators that they are not framed in the sole interest of the medical profession. They are unpopular with the public, as they interfere with the right of every American citizen to exercise perfect freedom in the selection of his medical adviser. To the mind of the educated physician the passage of such a law involves serious difficulties, to overcome which sacrifices must be conceded which imperil, if they do not completely counterbalance, the advantages which are supposed to be derived from it. Concessions must be made to, and the protecting influence of the law must be extended over, some of the very classes of practitioners it is proposed to reform. The States already recognize as "educated physicians" numerous sects professing belief in certain special systems of medicine, such as the eclectic, the homœopathic, the Thomsonian, the medico-botanical, etc., and are quite ready to admit into this category other practitioners without special forms of belief, or indeed of any particular education, who form themselves into associations with high-sounding titles, prepared ostentatiously to acknowledge the benefits of such a law and to claim its protection. In addition to all these there exist in this State the magnetic, the spiritualist, and medico-religious practitioners, who have a large and earnest following, whose claims would not be ignored by a committee having the bill in charge.⁴ In view of such possibilities the society may do well to ask itself whether it is fulfilling its duties to the public to advise the enactment of a law which will "galvanize into an appearance of temporary activity" numerous sects of varying degrees of vitality, or give even official recognition to that class of "healers" which constitutes a very large "part of the thing to be reformed."

It will be argued that these objections in no way invalidate the main feature of the bill, which establishes a standard of education to be secured by specified ex-

board should have full authority to 'go behind the returns,' and to reject any diploma when not satisfied that the person presenting such diploma has obtained it after pursuing some prescribed course of study, and *upon due examination*. The board should have authority to refuse and revoke licenses. A register of licentiates should be published annually. There should be provisions for licensing practitioners in other States living near the border; for permitting physicians to be called into the State in particular cases; for permitting such practice, under supervision, as is necessary for the education of students; for exempting United States medical officers, the medical officers of ships, and persons giving gratuitous medical advice in cases of emergency. The question of clairvoyant and magnetic physicians must be met in some way. The burden of prosecuting offenders under the law should rest on the legal officers of the State; not on the medical societies."

⁴ The spiritualists in this State number probably over one hundred thousand, and a large portion of these rely upon their prophets for medical as well as spiritual relief. There are to-day men without medical training who treat disease by virtue of the "psychic force" which they possess, who are honest in their belief, and have a large and intelligent class of patients. Some highly respectable people, to my personal knowledge, are treated after sending a lock of their hair to the "doctor." It is not necessary to dig deeply beneath the surface to find an amount of credulity and superstition comparable only to that which we read of in the history of the Middle Ages.

amination. To which it might be said in reply that no law could be passed, the penalties for non-compliance with which could not be evaded, and that we should thus be saddled with an act uncertain in its restraining, but quite positive in its protective, influences upon the "irregulars."¹ Those who were of the latter opinion might take the view that the society would more appropriately fulfill its mission by maintaining a high standard of education among those it admits to membership, thus making the contrast between the educated physician and irregular practitioner as striking as possible, than to busy itself with special protective legislation for practice and fees.

These are some of the aspects of a question the advocates of which, in no way discouraged by defeat, will urge again upon the Legislature at an early day. Upon such an important subject it will be advisable for the society to have an opinion, whether it may think best to take an active part in the discussion or not.

In this connection I would call your attention to a movement which is now going on within the society, and may lead eventually to important results.

In the numerous discussions which have taken place in recent years upon the question of admitting female practitioners to the society,² attention has frequently been drawn to the fact that no uniformity exists in the examinations conducted by the different boards of Censors throughout the State, and that the various boards have no means of communicating with another, or of comparing their work. An individual rejected by one of these boards may present himself for examination at some distant portion of the State, and be made a member of the society. Many of the boards, it was found recently, were ignorant of certain changes in the laws of the society. It is proposed that each board should hereafter report to the secretary of the society the names of all individuals who have failed to pass. It has also been suggested that a central committee be appointed to furnish certain information to the various boards, and that meetings of this committee, with delegates from each board, should be held at stated intervals. We have here the elements of an "educational section" of the society, from which a vast amount of valuable and interesting work might emanate, and to which might safely be intrusted the task of elaborating a plan which might offer a solution of some of the difficulties attending attempts to restrict the work of irregular practitioners. The society should not forget that it is through the efforts of some of its members that one of the most interesting experiments in medical education in this country is now being successfully completed; that the medical prestige of Massachusetts is to-day superior to that of any other State in the Union; and that any such work which should emanate from medical men in this State would be regarded as valuable authority. The subject is one of the important questions of the day; a free discussion by members of the society could hurt no one, and might be productive of valuable contributions to the cause.

The position of our society toward the treatment of insanity has always been one of cordial cooperation with those gentlemen of our profession who have devoted themselves to the difficult and troublesome duties of

asylum life in caring for the insane. The century's work in that respect is one of which we may be justly proud; our hospitals are among the few in the country which are free from political influences, and, through our distinguished members, Drs. Wyman and Bell, Massachusetts has stamped its mark upon the treatment of insanity throughout the country, and indeed to a very great extent in the Old World, through the effort of Miss Dix, who has carried our humane methods to England, Scotland, and, in a less degree, to the continent of Europe. More recently the society has shown a closer interest in insanity, as indicated by its investigations in regard to commitments to asylums, and by the fact that twelve of our number have taken upon themselves the arduous duty of being consulting physicians of the Danvers Hospital, two visiting together each month at least once. It is evident that it is not practicable to have visiting physicians in charge of insane asylums, while it is desirable to bring the interest of the profession to bear upon that important matter.

With the views of insanity held at the present time, somewhat different from those prevailing a quarter of a century ago, the work of the physician in general practice has widened as regards his relations to people suffering from mental disease. As it becomes better known, and is held more and more by the community to be simply a disease, more or less like other diseases, it will, whether treated in insane asylums or not, be each year to a greater extent advised upon by the practicing physician. The character of our institutions, too, must be changed to a considerable degree from being receptacles or boarding-houses for all kinds of mental deficiency to asylums for the incurable and hospitals in the strict sense of the word, with every appliance which art and science can afford for remedial treatment. In the discussion of this vast question our society can coöperate with the officers of the hospitals for the insane, and an enlightened public opinion which demands more scientific work, and help to place the whole subject in a better light before the community by increasing confidence where there is now unmerited distrust, by showing the falseness of exaggerated complaints, and by assisting all real progress and wise reform. The society is in a position to assist in guiding the legislation regarding insanity in a judicious direction, to help form opinion upon the best methods of improving our hospitals for the insane, and to raise the standard of professional and public knowledge of the causes and prevention of that obscure disease.

The unsatisfactory state of the laws relating to medical expert testimony has from time to time caused much discussion in this State, and cannot fail to have impressed every member of the society who has been called to the witness stand. It is, to say the least, an incongruity that his opinion, which, like that of the presiding officer, is judicial in its character, should be paid for, and to a certain extent controlled, by one of the parties to the suit, and that there should be no discrimination exercised in the selection of individuals who are expected to give testimony of a high scientific value. The abuses of this system are so many-sided, and such striking examples have occurred lately, that it is hardly necessary to draw your attention to them in detail.³

¹ It has been said that a large of those who originally fled from the State have returned to their respective States.

² No action has been taken by the writer to prevent the question of admitting female practitioners to the society. There is, however, no reason to believe that in the way of argument.

³ Among recent contributions to this subject may be mentioned articles by Professor Washburne, Transactions of the American Public Health Association, vol. iii.; Transactions of the Massachu-

In 1868 our society united with the American Academy of Arts and Sciences to present to the Legislature the draft of the law prepared by the late Hon. Emory Washburne, giving discretion to the court to appoint and require the attendance of one or more persons to be examined as experts. It was referred to the judiciary committee, but never came to light afterwards. A committee of the Massachusetts Medico-Legal Society, of which the attorney-general of the State was chairman, has within a year prepared the draft of a bill for legislative action. This bill provides "that in any action, suit, or proceeding, civil or criminal, in which the testimony of a medical expert witness is desired," the parties must make another agreement upon a suitable person, or if they fail to agree the court must appoint the same, upon whom a subpoena will then be served, and whose expenses will be paid by the court, the defeated party being liable to refund the amount. The court may also call other witnesses, if it so desires, and in a criminal case the defendant is allowed additional witnesses at his own cost.

At a meeting of the Boston Society for Medical Improvement, held last autumn, a committee was appointed to cooperate with other societies in this matter, and it was then suggested that the Massachusetts Medical Society possesses the element of organization out of which some plan might be evolved which should serve to determine more definitely the status of the medical expert.

It appears that the English method is open to abuse, like our own, while in Germany the law provides for official experts, and under the French plan the choice of the expert is left to the discretion of the court. In the last two countries, the medico-legal results are said to be admirable, and in striking contrast to the results with which we are familiar.

In connection with this subject, I would call the attention of the society to the extraordinary facility with which suits for malpractice are brought against reputable physicians, a form of business enterprise which, I regret to say, lawyers of the highest respectability in this city consider as perfectly legitimate work to be engaged in. Nothing is better calculated to bring the majesty of the law into disrepute than a system which permits, under the guise of legal processes, a rascally attack upon the pockets of a hard-working and innocent man, while the blunders of the ignorant quack are allowed to go unpunished. It has been suggested that judges should exercise some right of supervision, so that fraudulent suits should be prevented from obtaining a place on the dockets, or that all costs, including the defendant's counsel fees, should be paid by the plaintiff if he loses his case.¹ The society would do well to urge some such restrictive action.

The labors of those engaged in the department of experimental medicine have fortunately not yet been interfered with by the anti-vivisectionists. The great importance of this work in enabling us to acquire more accurate knowledge of the laws of health and disease is doubtless duly appreciated by members of the society. The study of medical science is still in its in-

fancy in this country, but a great deal of valuable original work has already been done, and the profession has reason to be proud of its record in this department. Still, a crusade, such as has swept over England, would strike a severe blow at further progress in medical knowledge. The public should be taught that this is a legitimate field of study, and one which has wrested from nature many valuable secrets. The Medical Society of the State of New York has set a good example to other societies in protecting her scientific men from attempts to interfere with their work by legislation. Repeated efforts to obtain such legislation have been foiled by the agency of individual members, who have promptly put their senators and representatives in possession of the facts of the case.

It has been the policy of the society of late years to offer, in addition to its time-honored certificate of membership, special advantages to each Fellow individually. The wisdom of this plan is shown in the thriving character of such associations as adopt the expedient. Volumes of Transactions, although extremely valuable in preserving an historical record of the society's work, cannot be placed in this category. On the other hand, a medical periodical included as part of the returns to be obtained from the annual assessment is something tangible, which becomes a connecting link to those members who, owing to circumstances, are unable to take an active part in the work of the society. The annual dinner has also proved a most useful feature in bringing together a larger number of members at one gathering than any other society can boast of, and in securing prompt payment of the society's dues. The excellent retrospect of medical science distributed to each member has been a popular and useful experiment. It gives to the busy member of the society valuable hints for use in practice, and affords interesting reading at the same time to the literary and scientific man. Like the patent food or nutritive enema, it administers its pabulum in a convenient and condensed form to those whose minds are intolerant of the more tedious processes by which the original article is usually administered.

The suggestion has, however, been made from several quarters, particularly from districts which depend chiefly upon the publications which the society offers, that a weekly periodical would be a more satisfactory form of journal, and that the patronage of native work would be more in keeping with the spirit and traditions of the society. The "semi-annual" and the "quarterly" are types of periodical literature which are gradually becoming extinct. Science moves too rapidly, and is too impatient of delay, to use such ponderous vehicles. A vigorous and progressive association like our own is hardly keeping up with the times in contenting itself with receiving the work of others at second hand and at long intervals, while it allows its own to be hidden in the volumes of Transactions. The same arguments which have been so frequently urged in behalf of a weekly journal for our National Association are equally true of each State society. Were a group of States like those of New England to unite upon a common medium of intercommunication, the stimulus to society work of all kinds would be immense, and the advantages of co-operation would bring with it great power. It will be a glorious day, both for medical societies and medical literature, in this country, when this principle becomes recognized.
